# DATA STRUCTURES

## MANAGING INFORMATION

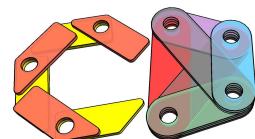

# IDLE

## INTEGRATED DEVELOPMENT & LEARNING ENVIRONMENT

This is the default development environment for python. It comes with python when you install it, and is suitable for beginners. Go to the start menu and start up IDLE. We'll begin learning the basics of python here.

The screenshot shows the Python 3.7.3 Shell window. The title bar reads "Python 3.7.3 Shell". The menu bar includes File, Edit, Shell, Debug, Options, Window, and Help. The main window displays the following text:  
Python 3.7.3 (v3.7.3:ef4ec6ed12, Mar 25 2019, 21:26  
:53) [MSC v.1916 32 bit (Intel)] on win32  
Type "help", "copyright", "credits" or "license()"  
for more information.  
>>> |

# VARIABLES

## ASSIGNING

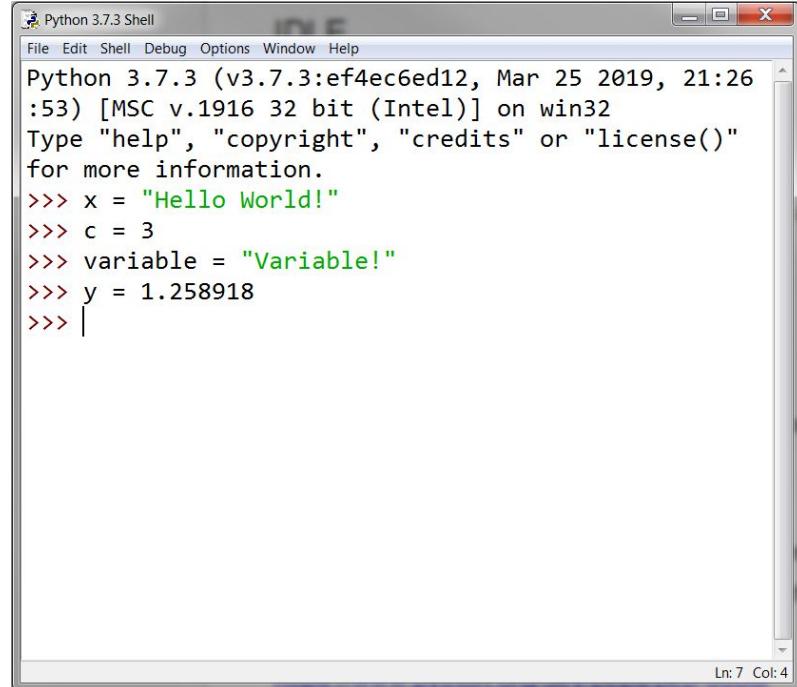

Similar to algebra, a variable is a shorthand name given to an object. Variables can be created from any data-type. Unlike other languages variables don't need to be given a type or declared in advanced.

Variables must start with a letter, but can contain letters, numbers, dashes, and underscores. Variables should be named so it's easy to identify what they're used for.

When you assign a variable python dynamically determines which data type it should be.

Every language has its own style conventions. We're not going to worry about it now, but you can read the official documentation:

<https://www.python.org/dev/peps/pep-0008/>

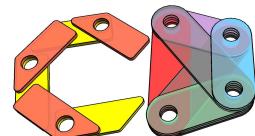

The screenshot shows the Python 3.7.3 Shell window. The title bar reads "Python 3.7.3 Shell". The menu bar includes File, Edit, Shell, Debug, Options, Window, and Help. The main area displays the following text:

```
Python 3.7.3 (v3.7.3:ef4ec6ed12, Mar 25 2019, 21:26 :53) [MSC v.1916 32 bit (Intel)] on win32
Type "help", "copyright", "credits" or "license()" for more information.

>>> x = "Hello World!"
>>> c = 3
>>> variable = "Variable!"
>>> y = 1.258918
>>> |
```

The bottom right corner of the window shows "Ln: 7 Col: 4".

# BASIC DATA TYPES

## NUMBERS

Any variable assigned to a number will be automatically be created as an integer. Technically there are several different kinds of numeric data types, which may be important to know

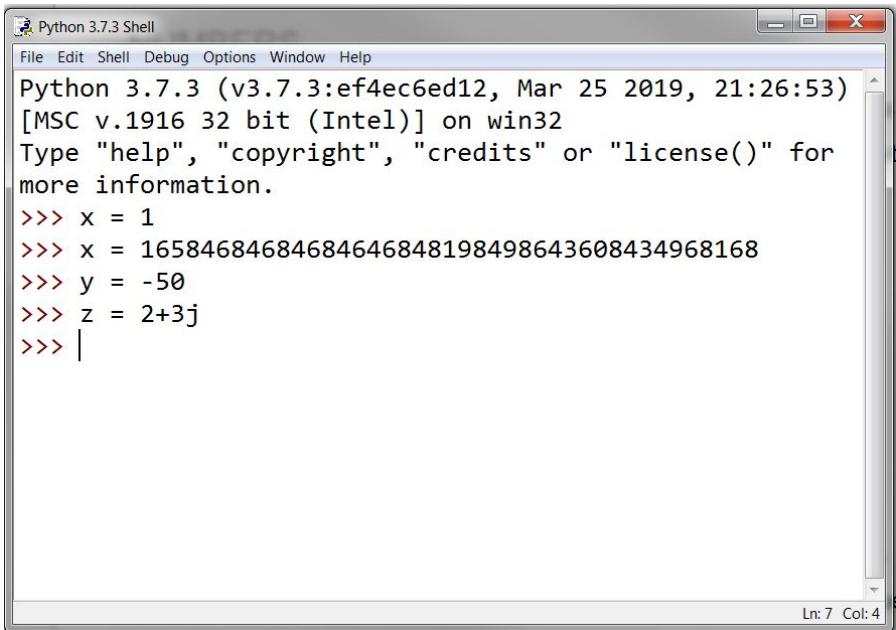

**integer (int)** : whole number - 5

**floating-point (float)** : decimal point number - 1.258

**complex**: <real number> + <imaginary number> - 2+3j

**long** : really long integers (this was phased out of python)

It's important to know about these special types of integers. For example float division is notoriously inaccurate. If you're dividing two decimals (floats) you may notice a tiny discrepancy with the output due to how computers calculate float division. Additionally, when dealing with older versions of python, such as what's used in Dynamo, you may find that a number is too big to be stored as an integer, and needs to be converted to a long type variable.

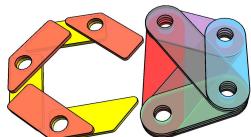

The screenshot shows a Windows-style window titled "Python 3.7.3 Shell". The menu bar includes File, Edit, Shell, Debug, Options, Window, and Help. The main area displays the Python interpreter's prompt (">>>>") followed by several lines of code and their outputs:

```
Python 3.7.3 (v3.7.3:ef4ec6ed12, Mar 25 2019, 21:26:53)
[MSC v.1916 32 bit (Intel)] on win32
Type "help", "copyright", "credits" or "license()" for
more information.

>>> x = 1
>>> x = 16584684684684646848198498643608434968168
>>> y = -50
>>> z = 2+3j
>>> |
```

In the bottom right corner of the window, there is a status bar with the text "Ln: 7 Col: 4".

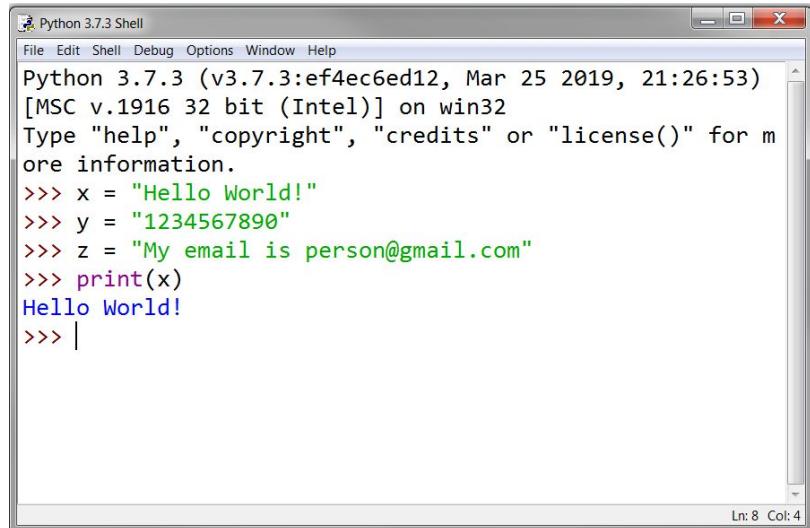

# BASIC DATA TYPES

## STRINGS

A sequence of characters (text) enclosed by either single ('') or double quotes (""). Strings can include any character such as letters, numbers, and symbols.

We'll go more into functions later, but the `print()` function is an important function to know. It will allow you to print the value of any string, including variables. This can be helpful when debugging, because it allows you to see the values of your variables at certain point in the code.

It's important to note that the backslash has special meaning in strings. It's called an escape character, and it's used to represent special characters. For example, a new line in a string can be represented by "\n".

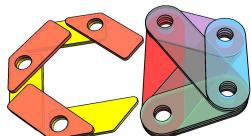

The screenshot shows a Windows-style window titled "Python 3.7.3 Shell". The menu bar includes File, Edit, Shell, Debug, Options, Window, and Help. The main area displays the Python interpreter's response to the following input:

```
Python 3.7.3 (v3.7.3:ef4ec6ed12, Mar 25 2019, 21:26:53)
[MSC v.1916 32 bit (Intel)] on win32
Type "help", "copyright", "credits" or "license()" for more information.

>>> x = "Hello World!"
>>> y = "1234567890"
>>> z = "My email is person@gmail.com"
>>> print(x)
Hello World!
>>> |
```

In the bottom right corner of the window, there is a status bar with "Ln: 8 Col: 4".

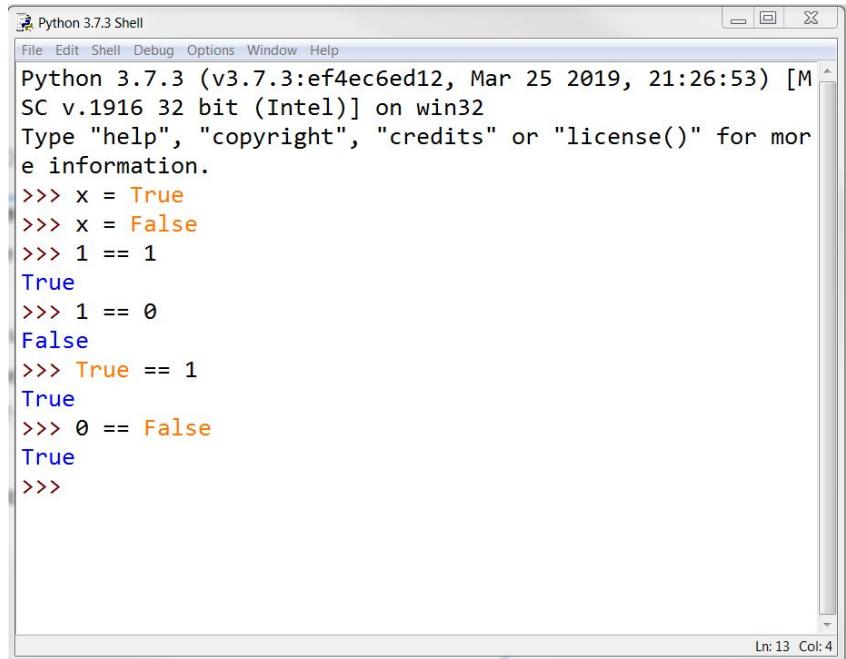

# BASIC DATA TYPES

## BOOLEAN (BOOL)

This data type is used to represent true or false values. Therefore they can either have a value of "True" or "False".

Boolean values are used a lot when evaluating expressions. For example, if you typed the expression `1==1` into python it would return True. Conversely, if you typed in `1==0` python would return False. (Technically equality is typed using double equals since a single equal sign sets the value of a variable.)

It's also interesting to note that 1 and True are equal to each other, as-is 0 and False.

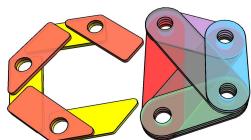

The screenshot shows a Python 3.7.3 Shell window. The console output demonstrates the equality of Boolean values and integers:

```
Python 3.7.3 (v3.7.3:ef4ec6ed12, Mar 25 2019, 21:26:53) [MSC v.1916 32 bit (Intel)] on win32
Type "help", "copyright", "credits" or "license()" for more information.

>>> x = True
>>> x = False
>>> 1 == 1
True
>>> 1 == 0
False
>>> True == 1
True
>>> 0 == False
True
>>>
```

The window has a title bar "Python 3.7.3 Shell", a menu bar with File, Edit, Shell, Debug, Options, Window, Help, and a status bar at the bottom right indicating "Ln: 13 Col: 4".

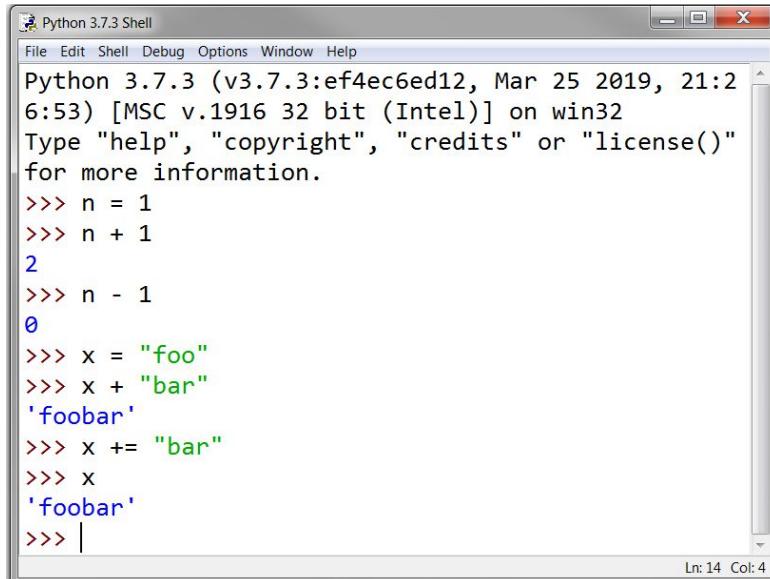

# BASIC DATA TYPES

## ADDITION / SUBTRACTION & CONCATENATION

Now that we have the basic data types, what can we do with them?

For integers, all typical mathematical operations can be performed on them. You can add or subtract, and python will act as a calculator.

Interestingly, you can also add strings together using the "+" character. This is called concatenation. Using the "+=" symbols together will add the additional characters to the value of your variable.

The screenshot shows the Python 3.7.3 Shell window. It displays the Python version information and a few examples of arithmetic and string manipulation:

```
Python 3.7.3 (v3.7.3:ef4ec6ed12, Mar 25 2019, 21:2  
6:53) [MSC v.1916 32 bit (Intel)] on win32  
Type "help", "copyright", "credits" or "license()"  
for more information.  
>>> n = 1  
>>> n + 1  
2  
>>> n - 1  
0  
>>> x = "foo"  
>>> x + "bar"  
'foobar'  
>>> x += "bar"  
>>> x  
'foobar'  
>>> |
```

Ln: 14 Col: 4

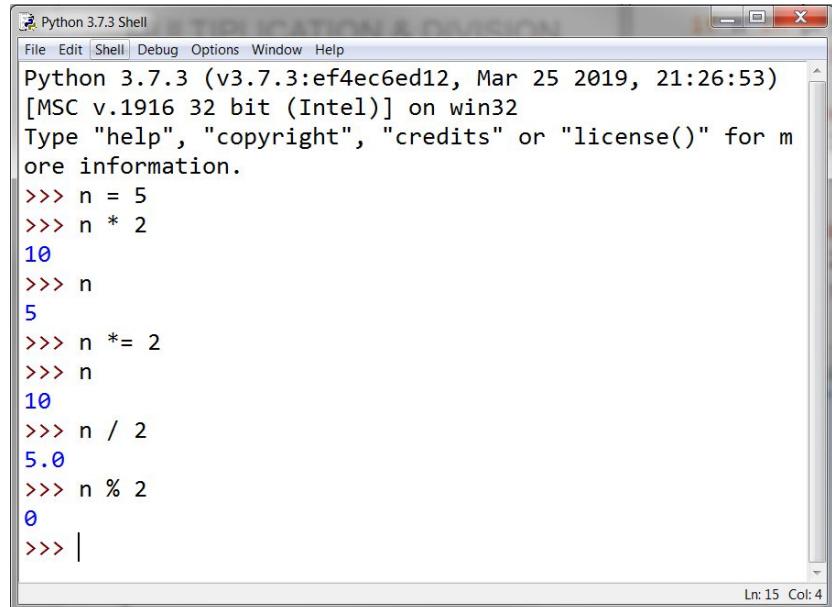

# BASIC DATA TYPES

## MULTIPLICATION & DIVISION

You can also use the multiply and divide operations. As with other programs “\*” is multiply and “/” is divide. Just like with addition you can group those signs with an equal sign to set your variable equal to the multiplication or division of the value.

There is an additional operation that may be helpful to know. The symbol “/” returns the result of a division between two values. There is also an additional using the “%” character that returns the remainder of division between two numbers. You could use this to check if a number is even.

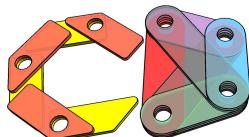

The screenshot shows a Python 3.7.3 Shell window. The title bar reads "Python 3.7.3 Shell". The menu bar includes File, Edit, Shell, Debug, Options, Window, and Help. The main window displays the following Python session:

```
Python 3.7.3 (v3.7.3:ef4ec6ed12, Mar 25 2019, 21:26:53)
[MSC v.1916 32 bit (Intel)] on win32
Type "help", "copyright", "credits" or "license()" for more information.

>>> n = 5
>>> n * 2
10
>>> n
5
>>> n *= 2
>>> n
10
>>> n / 2
5.0
>>> n % 2
0
>>> |
```

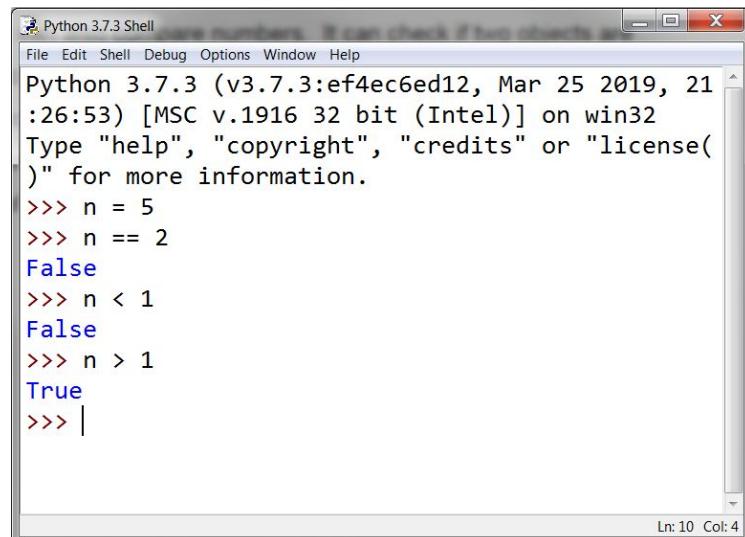

The status bar at the bottom right indicates "Ln: 15 Col: 4".

# BASIC DATA TYPES

## COMPARISONS

Python can also compare numbers. It can check if two objects are equal to each other “==”, if an operand is less than another “<”, or if an operand is greater than another “>”. You can also combine them to get less than or equal to “>=” or greater than or equal to “<=”. The result of these comparisons will be a boolean (True or False) value.

The screenshot shows the Python 3.7.3 Shell window. The title bar reads "Python 3.7.3 Shell". The menu bar includes File, Edit, Shell, Debug, Options, Window, and Help. The main window displays the following code and output:

```
Python 3.7.3 (v3.7.3:ef4ec6ed12, Mar 25 2019, 21:26:53) [MSC v.1916 32 bit (Intel)] on win32
Type "help", "copyright", "credits" or "license()" for more information.

>>> n = 5
>>> n == 2
False
>>> n < 1
False
>>> n > 1
True
>>> |
```

In the bottom right corner of the shell window, there is a status bar with "Ln: 10 Col: 4".

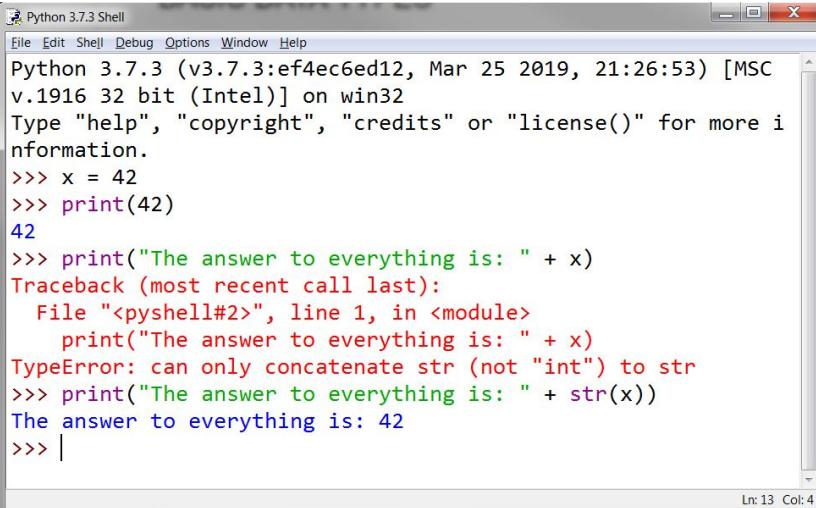

# BASIC DATA TYPES

## TYPE CONVERSION

Some data types can be converted to other types. Most of the time you will be converting an integer or boolean to a string. If you want to print the value of an integer along with other text you'll need to convert it to a string using this function `str(int)`.

Converting a string to an integer is a little more complicated, because not all strings contain integers. That's beyond the scope of this course.

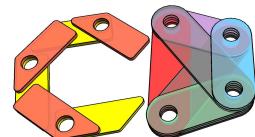

The screenshot shows a Python 3.7.3 Shell window. The console output is as follows:

```
Python 3.7.3 (v3.7.3:ef4ec6ed12, Mar 25 2019, 21:26:53) [MSC v.1916 32 bit (Intel)] on win32
Type "help", "copyright", "credits" or "license()" for more information.

>>> x = 42
>>> print(42)
42

>>> print("The answer to everything is: " + x)
Traceback (most recent call last):
  File "<pyshell#2>", line 1, in <module>
    print("The answer to everything is: " + x)
TypeError: can only concatenate str (not "int") to str
>>> print("The answer to everything is: " + str(x))
The answer to everything is: 42
>>> |
```

The window has a title bar "Python 3.7.3 Shell", a menu bar with "File", "Edit", "Shell", "Debug", "Options", "Window", and "Help", and a status bar at the bottom right indicating "Ln: 13 Col: 4".

# ADVANCED DATA TYPES

## LIST

A list is an ordered sequence of elements. A list can contain any other data type, and they can be combined. It's possible to create a list of integers, strings, or boolean values. You could even create a list of lists!

You can create an empty list by assigning a variable to an open and closed bracket "[]". When you create the list you can define its initial values by separating each value with a comma.

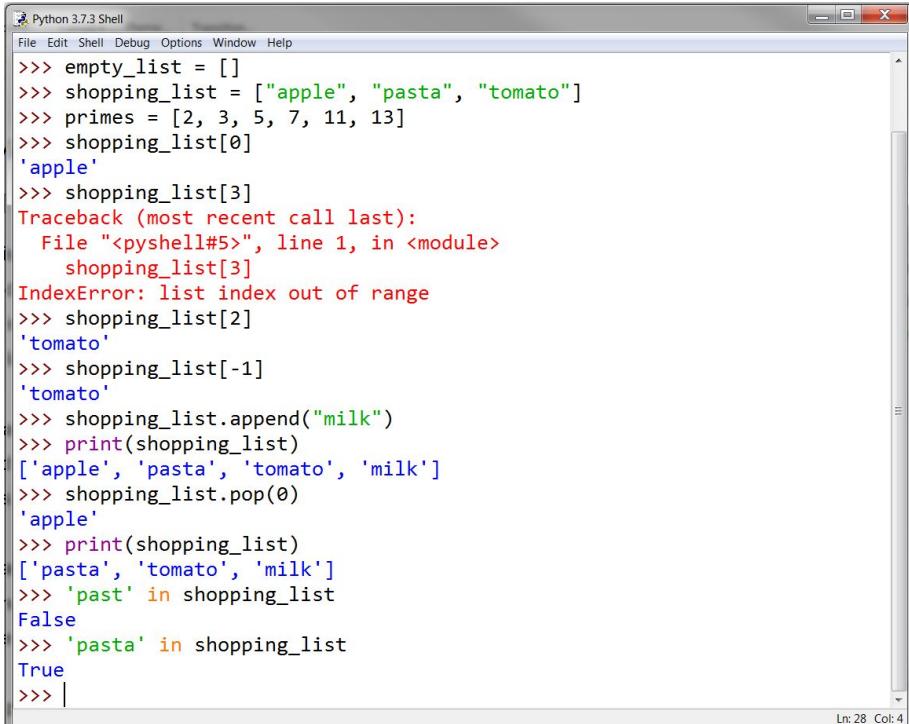

Lists are mutable, meaning that they can be changed. You can add or remove items from a list. It's important to note that elements in the list are in a specific order, but the list can be re-ordered.

The append method can be used to append an item to a list.

```
my_list.append("New Item")
```

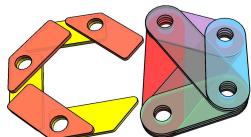

The pop method can be used to remove an item using it's index

```
my_list.pop(0)
```

The screenshot shows a Python 3.7.3 Shell window. The code demonstrates various list operations:

```
>>> empty_list = []
>>> shopping_list = ["apple", "pasta", "tomato"]
>>> primes = [2, 3, 5, 7, 11, 13]
>>> shopping_list[0]
'apple'
>>> shopping_list[3]
Traceback (most recent call last):
  File "<pyshell#5>", line 1, in <module>
    shopping_list[3]
IndexError: list index out of range
>>> shopping_list[2]
'tomato'
>>> shopping_list[-1]
'tomato'
>>> shopping_list.append("milk")
>>> print(shopping_list)
['apple', 'pasta', 'tomato', 'milk']
>>> shopping_list.pop(0)
'apple'
>>> print(shopping_list)
['pasta', 'tomato', 'milk']
>>> 'past' in shopping_list
False
>>> 'pasta' in shopping_list
True
>>>
```

# ADVANCED DATA TYPES

## LIST

Since lists are sequences of elements you can iterate through all the elements in a list. You can also select an element from a list by its index. The index is the order in which an item appears in the list. It's important to note that the index starts at zero. To get the value of the first item in a list you would type `my_list[0]`.

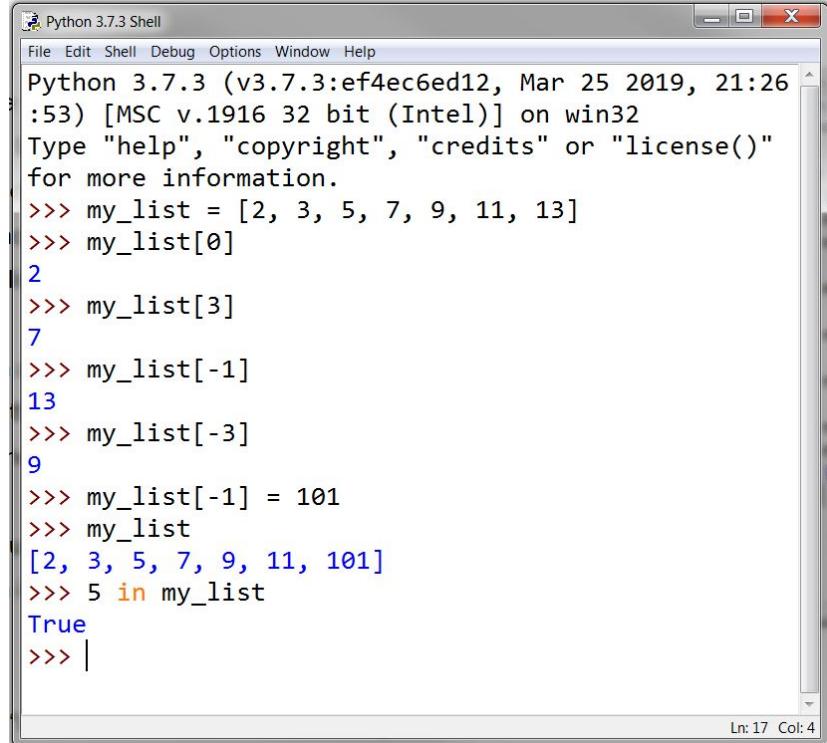

Elements can also be indexed from the end of the list using a negative index. Since the first item in the list is 0 then last item would be -1.

You can get the last item in the list by typing `my_list[-1]`.

You can also use the index to change the value of an object in a list, and re-assign it to a different value:

```
my_list[0] = 5
```

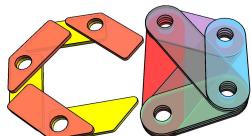

The keyword "in" can be used to determine if a given object is contained in a list

A screenshot of the Python 3.7.3 Shell window. The title bar says "Python 3.7.3 Shell". The menu bar includes File, Edit, Shell, Debug, Options, Window, and Help. The main area shows the following Python session:

```
Python 3.7.3 (v3.7.3:ef4ec6ed12, Mar 25 2019, 21:26  
:53) [MSC v.1916 32 bit (Intel)] on win32  
Type "help", "copyright", "credits" or "license()"  
for more information.  
>>> my_list = [2, 3, 5, 7, 9, 11, 13]  
>>> my_list[0]  
2  
>>> my_list[3]  
7  
>>> my_list[-1]  
13  
>>> my_list[-3]  
9  
>>> my_list[-1] = 101  
>>> my_list  
[2, 3, 5, 7, 9, 11, 101]  
>>> 5 in my_list  
True  
>>> |
```

Ln: 17 Col: 4

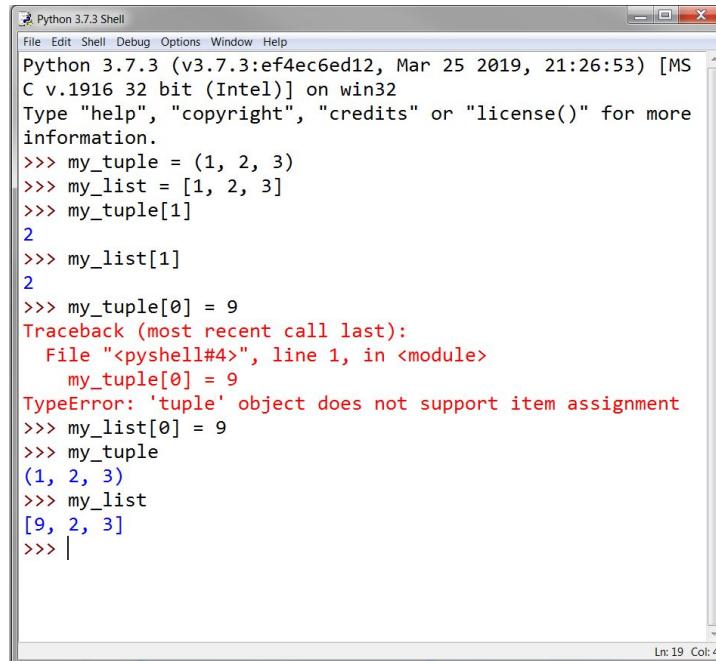

# ADVANCED DATA TYPES

## Tuple

Tuples aren't used very often, but it's good to know what they are. A tuple is the same thing as a list except that tuples are immutable. This means that they can't change after they have been created.

Tuples are created by defining them with parenthesis:

```
my_tuple = (1, 2, 3)
```

The screenshot shows a Python 3.7.3 Shell window. The code demonstrates that tuples are immutable. It creates a tuple `my_tuple` and a list `my_list` with identical elements. It then attempts to change the first element of `my_tuple` to 9, which results in a `TypeError`. The list `my_list` is modified successfully.

```
Python 3.7.3 (v3.7.3:ef4ec6ed12, Mar 25 2019, 21:26:53) [MSC v.1916 32 bit (Intel)] on win32
Type "help", "copyright", "credits" or "license()" for more information.
>>> my_tuple = (1, 2, 3)
>>> my_list = [1, 2, 3]
>>> my_tuple[1]
2
>>> my_list[1]
2
>>> my_tuple[0] = 9
Traceback (most recent call last):
  File "<pyshell#4>", line 1, in <module>
    my_tuple[0] = 9
TypeError: 'tuple' object does not support item assignment
>>> my_list[0] = 9
>>> my_tuple
(1, 2, 3)
>>> my_list
[9, 2, 3]
>>> |
```

# ADVANCED DATA TYPES

## DICTIONARY

A dictionary is similar to a list in that it is a sequence of elements; however, each element in a dictionary has a key and a value pair. For every key in a dictionary there will be a corresponding value. Just like how every word in a dictionary has definition. Keys and values can be any data type.

Dictionaries are defined with curly braces "{}". To create a new variable as an empty dictionary you would type my\_dictionary = {}.

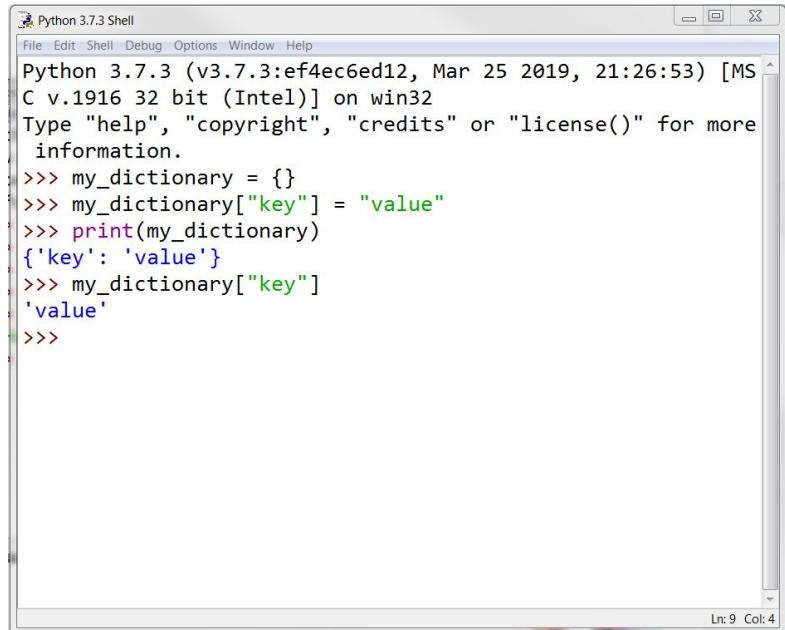

You can also define initial values when you create the dictionary:

```
my_dictionary = { "foo" : "bar", "green" : "blue", "Hello" : "World"}
```

You add elements to a dictionary by defining the key and setting its value:

```
my_dictionary["key"] = "value"
```

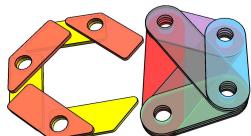

The above code would add a key called "key", with a corresponding value of "value"

The screenshot shows a Python 3.7.3 Shell window. The shell displays the following code and output:

```
Python 3.7.3 (v3.7.3:ef4ec6ed12, Mar 25 2019, 21:26:53) [MS
C v.1916 32 bit (Intel)] on win32
Type "help", "copyright", "credits" or "license()" for more
information.

>>> my_dictionary = {}
>>> my_dictionary["key"] = "value"
>>> print(my_dictionary)
{'key': 'value'}
>>> my_dictionary["key"]
'value'
>>>
```

# ADVANCED DATA TYPES

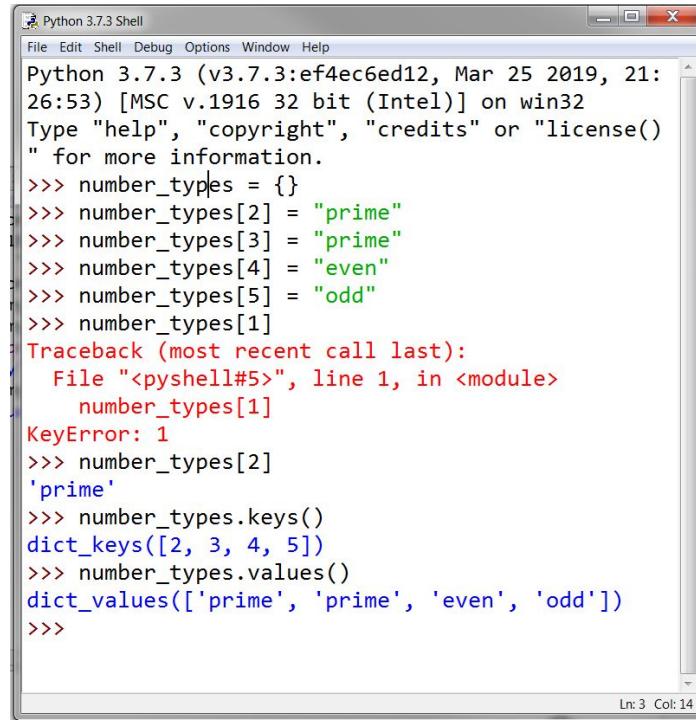

## DICTIONARY

Elements in a dictionary are retrieved by indexing their key. If you have a key of 2 in your dictionary you can use the index 2 to retrieve the corresponding value.

You can use the method `keys()` to get all the keys in the dictionary. Similarly, you can use the method `values()` to get all the values.

It was mentioned that dictionaries are sequences. It's important to know that unlike lists dictionaries have no order. If you retrieve all the keys of a dictionary the order may not always be the same.

Similar to lists you can iterate over all the keys in a dictionary.

The screenshot shows a Python 3.7.3 Shell window. The code defines a dictionary `number_types` with keys 2, 3, 4, and 5, and values 'prime', 'prime', 'even', and 'odd' respectively. When trying to access key 1, it raises a `KeyError: 1`. The command `number_types.keys()` returns a list of keys [2, 3, 4, 5], and `number_types.values()` returns a list of values ['prime', 'prime', 'even', 'odd']. The window has a title bar "Python 3.7.3 Shell", a menu bar "File Edit Shell Debug Options Window Help", and status text "Ln: 3 Col: 14" at the bottom right.

```
Python 3.7.3 (v3.7.3:ef4ec6ed12, Mar 25 2019, 21:26:53) [MSC v.1916 32 bit (Intel)] on win32
Type "help", "copyright", "credits" or "license()"
" for more information.

>>> number_types = {}
>>> number_types[2] = "prime"
>>> number_types[3] = "prime"
>>> number_types[4] = "even"
>>> number_types[5] = "odd"
>>> number_types[1]
Traceback (most recent call last):
  File "<pyshell#5>", line 1, in <module>
    number_types[1]
KeyError: 1
>>> number_types[2]
'prime'
>>> number_types.keys()
dict_keys([2, 3, 4, 5])
>>> number_types.values()
dict_values(['prime', 'prime', 'even', 'odd'])
>>>
```

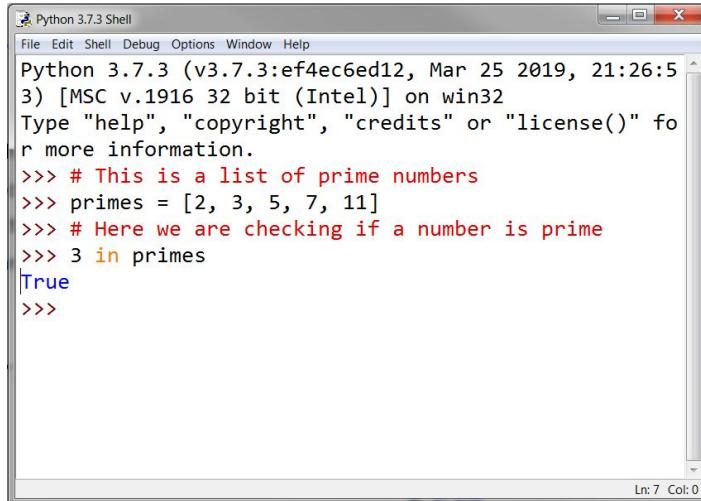

# ADVANCED DATA TYPES

## COMMENTS

Comments are notes to the person who is reading your code. It's helpful to write a lot of comments in your code so that you or somebody else can understand what the code is doing when you look back at it months or years later. Commenting your code is really important.

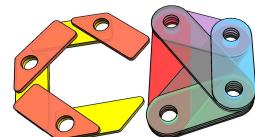

In python a comment is defined by "#". Anything following that character is a comment.

The screenshot shows the Python 3.7.3 Shell window. The title bar reads "Python 3.7.3 Shell". The menu bar includes File, Edit, Shell, Debug, Options, Window, and Help. The main window displays the following Python session:

```
Python 3.7.3 (v3.7.3:ef4ec6ed12, Mar 25 2019, 21:26:55
3) [MSC v.1916 32 bit (Intel)] on win32
Type "help", "copyright", "credits" or "license()" for more information.
>>> # This is a list of prime numbers
>>> primes = [2, 3, 5, 7, 11]
>>> # Here we are checking if a number is prime
>>> 3 in primes
True
>>>
```

The status bar at the bottom right indicates "Ln: 7 Col: 0".

# CONTROL STRUCTURES

## PROGRAM FLOW

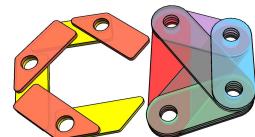

# CONTROL STRUCTURES

## CONDITIONAL STATEMENTS & LOOPS

Most of the work done by the code is done through control structures.

Python scripts, and all code in general, executes sequentially.

Control structures allow you to define when certain parts of the code should run, and allow you to loop over the code multiple times to run the same operation of a list of elements. Control structures are what allow you to do that.

# CONTROL STRUCTURES

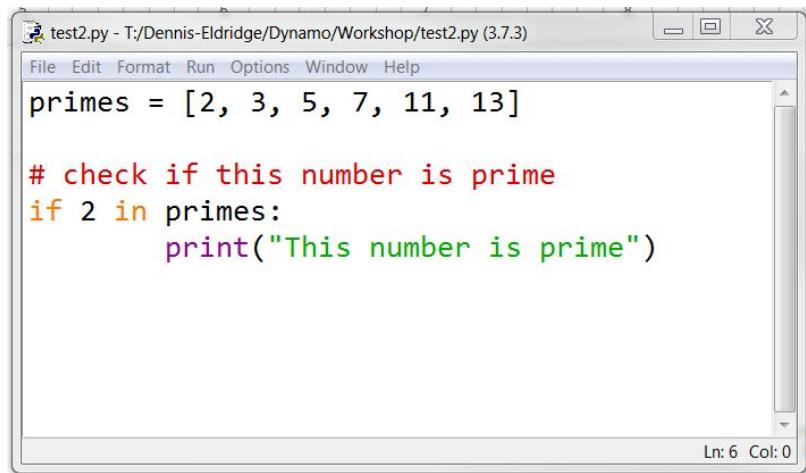

## IF THEN

The if then control structures defines some condition in which the subsequent code will run. Here is the format:

if condition:

    conditional code

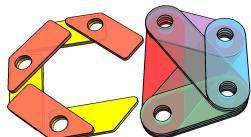

Python is very particular about the format so it's important to take note of a few things. The if statement always starts with a lowercase if. The condition must evaluate to a True or False statement, and it must end with a colon “:”. If the condition is true it will run the conditional code. The conditional code **must** be indented by either 1 tab or 4 spaces or Python will return an error.

```
test2.py - T:/Dennis-Eldridge/Dynamo/Workshop/test2.py (3.7.3)
File Edit Format Run Options Window Help
primes = [2, 3, 5, 7, 11, 13]

# check if this number is prime
if 2 in primes:
    print("This number is prime")
```

Ln: 6 Col: 0

# CONTROL STRUCTURES

## IF THEN ELSE

If the condition is False, then it may be useful to do something different. In this case you can use the else statement following the conditional code. Here is the format:

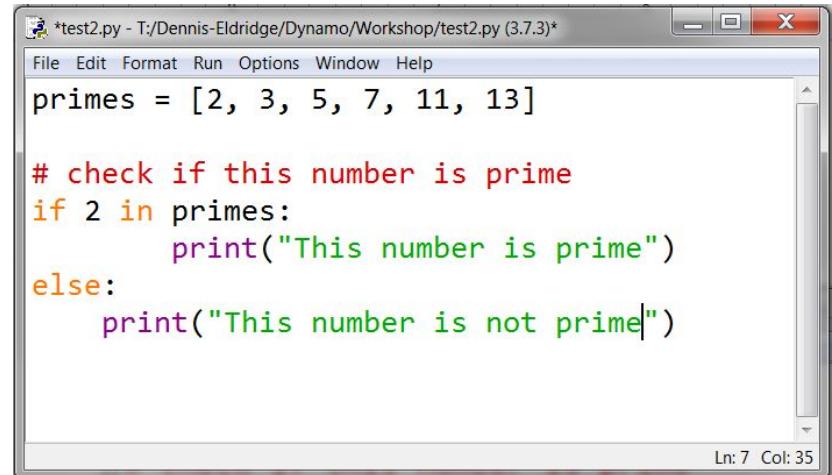

if condition:

    conditional code

else:

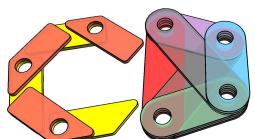

    conditional code

As you can see if the condition is false then the else conditional code will run. The else statement must be on the same line as the if statement, and must be followed by a colon “:”. Any conditional code following the else statement must be indented by 1 tab or 4 spaces.

```
*test2.py - T:/Dennis-Eldridge/Dynamo/Workshop/test2.py (3.7.3)*
File Edit Format Run Options Window Help
primes = [2, 3, 5, 7, 11, 13]

# check if this number is prime
if 2 in primes:
    print("This number is prime")
else:
    print("This number is not prime|")
```

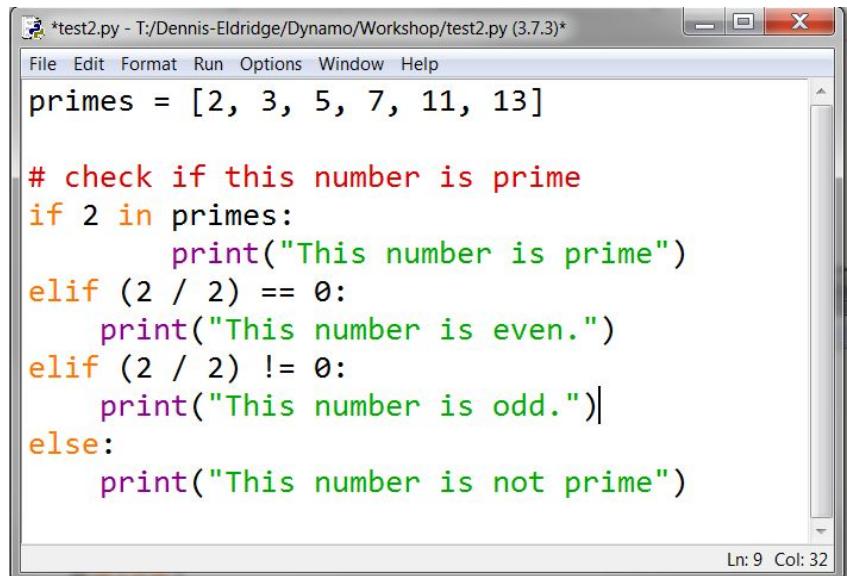

# CONTROL STRUCTURES

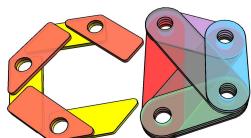

## IF THEN ELIF ELSE

What if you want to test multiple conditions? Python has an elif statement that will run if the first statement is false. You can have as many elif statements as you want. After all your elif statements you can have a final else statement. The format is similar to the if statement:

```
if condition:  
    conditional code  
elif condition:  
    conditional code  
elif condition:  
    conditional code  
else:  
    conditional code
```

```
*test2.py - T:/Dennis-Eldridge/Dynamo/Workshop/test2.py (3.7.3)*  
File Edit Format Run Options Window Help  
primes = [2, 3, 5, 7, 11, 13]  
  
# check if this number is prime  
if 2 in primes:  
    print("This number is prime")  
elif (2 / 2) == 0:  
    print("This number is even.")  
elif (2 / 2) != 0:  
    print("This number is odd.")  
else:  
    print("This number is not prime")  
  
Ln: 9 Col: 32
```

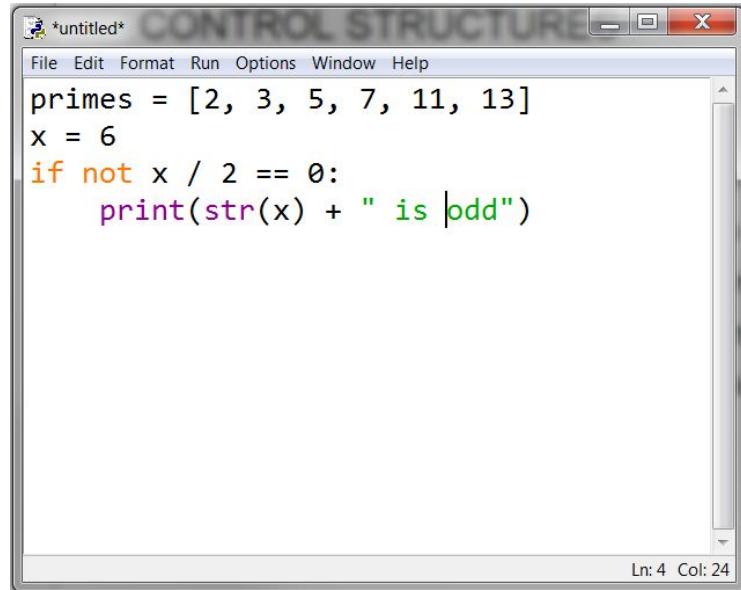

# CONTROL STRUCTURES

## NOT

Python also has a few addition options for more complex and powerful conditional statements. These are the logical “and”, “or”, and “not”. Those of you use use a lot of filters may be familiar with how they work. The not statement simply inverts the boolean value. not True would equal False, and not False would equal True

Truth table	
X	NOT X
False	True
True	False

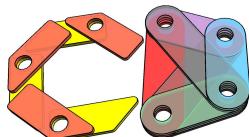

```
*untitled* CONTROL STRUCTURE
File Edit Format Run Options Window Help
primes = [2, 3, 5, 7, 11, 13]
x = 6
if not x / 2 == 0:
    print(str(x) + " is odd")
```

The screenshot shows a Windows-style code editor window titled "untitled". The menu bar includes File, Edit, Format, Run, Options, Window, and Help. The code area contains the following Python script:

```
primes = [2, 3, 5, 7, 11, 13]
x = 6
if not x / 2 == 0:
    print(str(x) + " is odd")
```

The status bar at the bottom right indicates "Ln: 4 Col: 24".

# CONTROL STRUCTURES

## AND

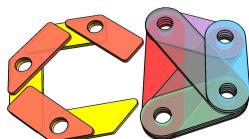

For an “and” statement to be true both operators need to be true.

Truth table		
X	Y	X AND Y
False	False	False
False	True	False
True	False	False
True	True	True

```
*test2.py - T:/Dennis-Eldridge/Dynamo/Workshop/test2.py (3.7.3)*
File Edit Format Run Options Window Help
primes = [2, 3, 5, 7, 11, 13]

# check if this number is prime
if 2 in primes:
    print("This number is prime")
elif (2 / 2) == 0:
    print("This number is even.")
elif (2 / 2) != 0:
    print("This number is odd.")
else:
    print("This number is not prime")

Ln: 9 Col: 32
```

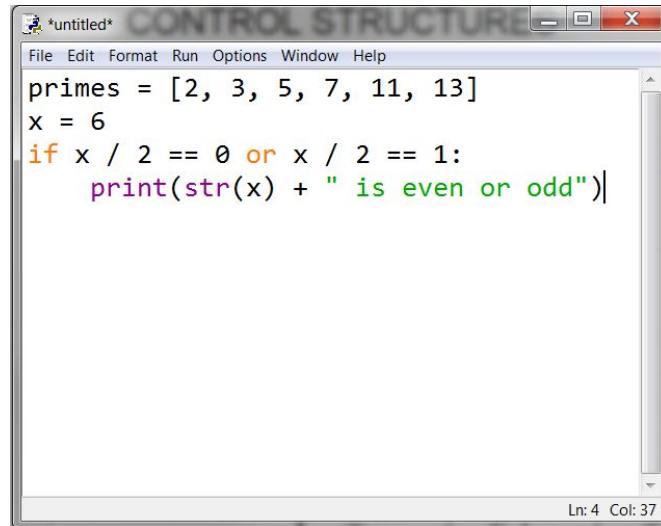

# CONTROL STRUCTURES

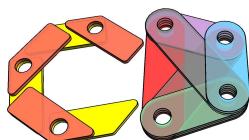

OR

Or statements are true if either or both of the operators are true

Truth table		
X	Y	X OR Y
False	False	False
False	True	True
True	False	True
True	True	True

```
*untitled* CONTROL STRUCTURE
File Edit Format Run Options Window Help
primes = [2, 3, 5, 7, 11, 13]
x = 6
if x / 2 == 0 or x / 2 == 1:
    print(str(x) + " is even or odd")
Ln: 4 Col: 37
```

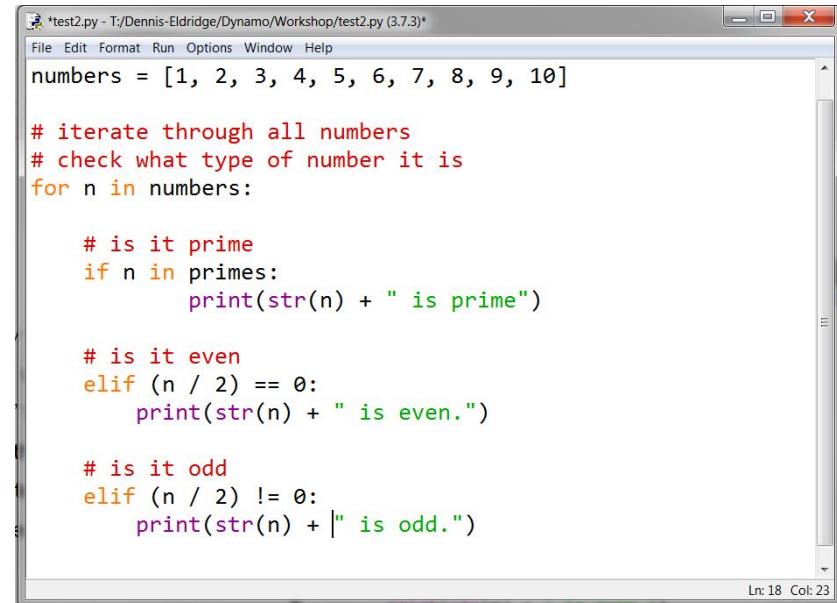

# CONTROL STRUCTURES

## FOR LOOP

The next control structure, the “for” loop, will allow you to iterate over every value in a list. The syntax of “for” loops are very similar to that of “if” statements. You start with the keyword “for” then you define a variable for the instance of the list you will iterate through (n below), and then you write “in” which list you want to iterate over. Similar to an “if” statement any code within the “for” loop needs to be indented with 1 tab or 4 spaces.

for variable in list:

    iterative statements on variable

```
*test2.py - T:/Dennis-Eldridge/Dynamo/Workshop/test2.py (3.7.3)*
File Edit Format Run Options Window Help
numbers = [1, 2, 3, 4, 5, 6, 7, 8, 9, 10]

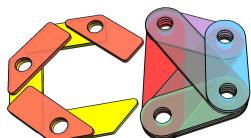

# iterate through all numbers
# check what type of number it is
for n in numbers:

    # is it prime
    if n in primes:
        print(str(n) + " is prime")

    # is it even
    elif (n / 2) == 0:
        print(str(n) + " is even.")

    # is it odd
    elif (n / 2) != 0:
        print(str(n) + " is odd.")

Ln: 18 Col: 23
```

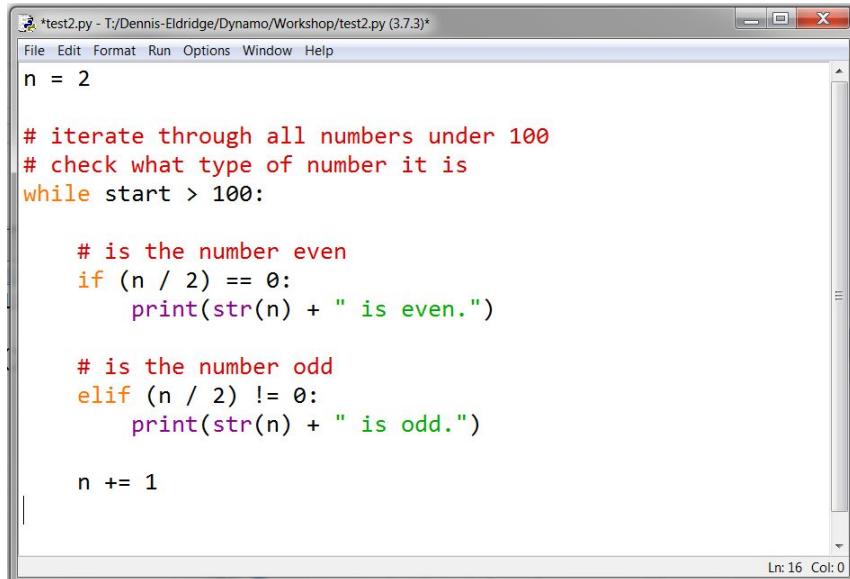

# CONTROL STRUCTURES

## WHILE LOOP

A while loop is a mix between a for loop and a conditional statement. It will keep iterating as long as some condition is true. You need to be careful with your conditions when creating while loops, because it's possible to create infinite loops if the conditional statement never becomes false. As you can see below the syntax for while statements are similar to the other control structures. Here is the format of while statements:

while condition:

    conditional statements

The screenshot shows a Windows-style code editor window titled "test2.py - T:/Dennis-Eldridge/Dynamo/Workshop/test2.py (3.7.3)". The menu bar includes File, Edit, Format, Run, Options, Window, and Help. The code in the editor is as follows:

```
n = 2

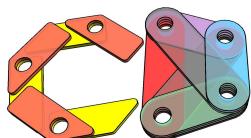

# iterate through all numbers under 100
# check what type of number it is
while start > 100:

    # is the number even
    if (n / 2) == 0:
        print(str(n) + " is even.")

    # is the number odd
    elif (n / 2) != 0:
        print(str(n) + " is odd.")

    n += 1
```

The status bar at the bottom right indicates "Ln: 16 Col: 0".

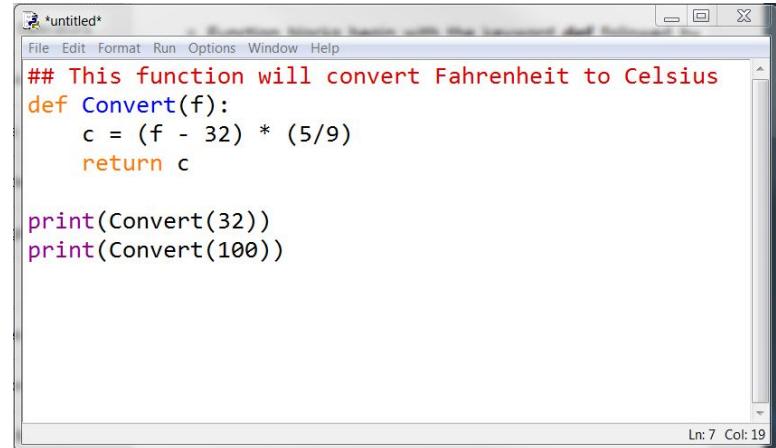

# CONTROL STRUCTURES

## FUNCTIONS

A function is a similar to a formula in math. It's a predefined sequence of operations that output some value, or make some change to the data. Functions are really useful for some action that needs to be repeated a large number of times. Using them can also make your code easier to read. Here is the syntax for a function:

```
def FunctionName(input):
    function code
    return output
```

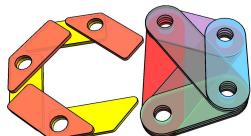

Functions start with the “def” keyword followed by the name of the function. Then you need two parentheses followed by a colon. If the function takes any input then you list each input variable name separated by a comma. Then you’ll indent and write your code for the function. A function can return a value or variable, which is indicated with the “return” keyword.

```
## This function will convert Fahrenheit to Celsius
def Convert(f):
    c = (f - 32) * (5/9)
    return c

print(Convert(32))
print(Convert(100))
```

The screenshot shows a Windows-style code editor window titled "untitled\*". The menu bar includes File, Edit, Format, Run, Options, Window, and Help. The code in the editor is written in Python. It defines a function named "Convert" that takes a parameter "f" and returns the converted value "c" using the formula  $c = (f - 32) * (5/9)$ . Two calls to the "Convert" function are made: one for 32 and one for 100. The status bar at the bottom right indicates "Ln: 7 Col: 19".

# CLASSES

## BRINGING IT ALL TOGETHER

# CLASSES

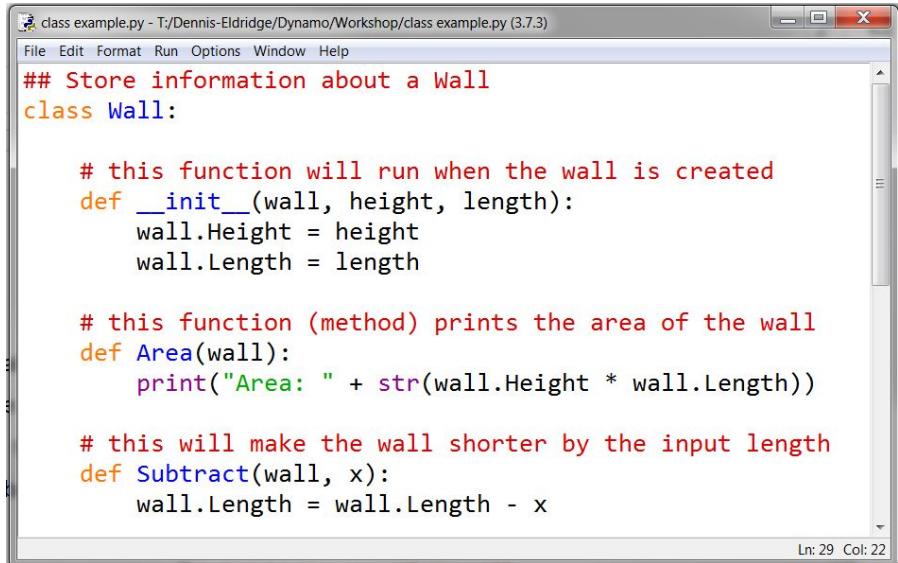

## DEFINITION

are a collection of all the things that we've talked about thus far. You can think of it as a template that is predefined to contain specific variables and functions that helps to group information, perform an action, or both. Classes are defined with the this syntax:

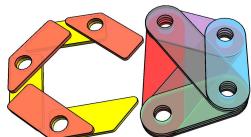

```
class ClassName:
```

```
    def __init__(self):  
        Initialization code
```

Properties of the class are defined as the wall class.Property.  
Functions within a class are called methods, and are accessed as  
class.Method() with parenthesis.

```
## Store information about a Wall  
class Wall:  
  
    # this function will run when the wall is created  
    def __init__(wall, height, length):  
        wall.Height = height  
        wall.Length = length  
  
    # this function (method) prints the area of the wall  
    def Area(wall):  
        print("Area: " + str(wall.Height * wall.Length))  
  
    # this will make the wall shorter by the input length  
    def Subtract(wall, x):  
        wall.Length = wall.Length - x
```

# CLASSES

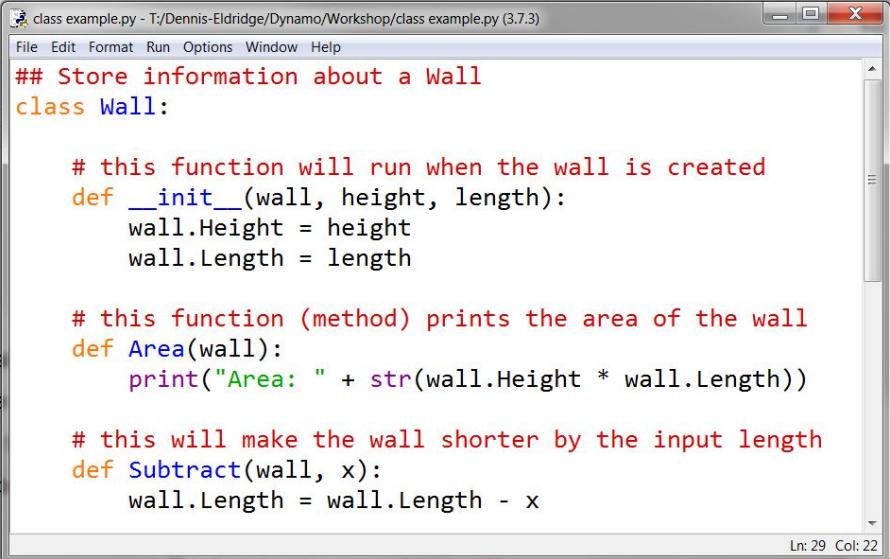

## CREATION

In the `__init__` function we noted the `self` variable. That variable is used to define properties of the class. If you use the variable name, and then a period that will create a property of the class with that name, which you can then define a value. This value could be changed later.

```
def __init__(self):
    self.Parameter = value
```

Within your class you can also define functions. Functions within a class are defined the same way you would define them outside a class. A function within a class is referred to as a method. The first parameter of a function has to be the `self` variable followed by a comma separated list of optional variables.

```
def Action(self):
    return code
```

The screenshot shows a window titled "class example.py - T:/Dennis-Eldridge/Dynamo/Workshop/class example.py (3.7.3)". The menu bar includes File, Edit, Format, Run, Options, Window, and Help. The code in the editor is:

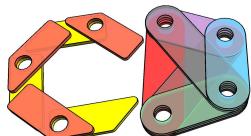

```
## Store information about a Wall
class Wall:

    # this function will run when the wall is created
    def __init__(wall, height, length):
        wall.Height = height
        wall.Length = length

    # this function (method) prints the area of the wall
    def Area(wall):
        print("Area: " + str(wall.Height * wall.Length))

    # this will make the wall shorter by the input length
    def Subtract(wall, x):
        wall.Length = wall.Length - x
```

Ln: 29 Col: 22

# CLASSES

## INITIALIZATION

Once the class is defined you can create instances from the class template by assigning the class to a variable like so:

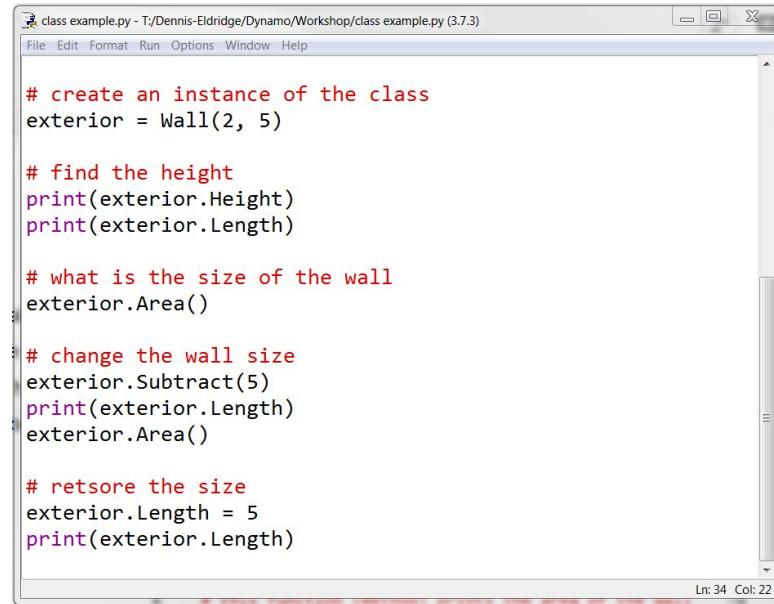

```
exterior = Wall(2, 5)
```

Once the instance of the class is created you can access the properties of the class with a period, and the name of the property

```
exterior.Height
```

You can access the method of the class by using a period, and then the name of the function. For a method you'll also need parentheses and any required parameters

```
exterior.Area()
```

```
# create an instance of the class
exterior = Wall(2, 5)

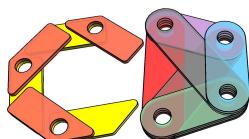

# find the height
print(exterior.Height)
print(exterior.Length)

# what is the size of the wall
exterior.Area()

# change the wall size
exterior.Subtract(5)
print(exterior.Length)
exterior.Area()

# restore the size
exterior.Length = 5
print(exterior.Length)
```

Ln: 34 Col: 22

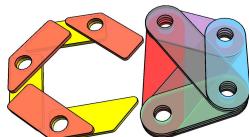

# CLASSES

## REVIEW

Don't worry if you get confused about how to create a class. Class creation is not necessary in the vast majority of cases for Dynamo. It's important to know how classes work though, because everything in the Revit API is a class.

It's important to remember that a class is a template used to represent a type of object. Classes contain properties which contain useful values, and methods that return some value, or take some action on the class.

# CLASSES

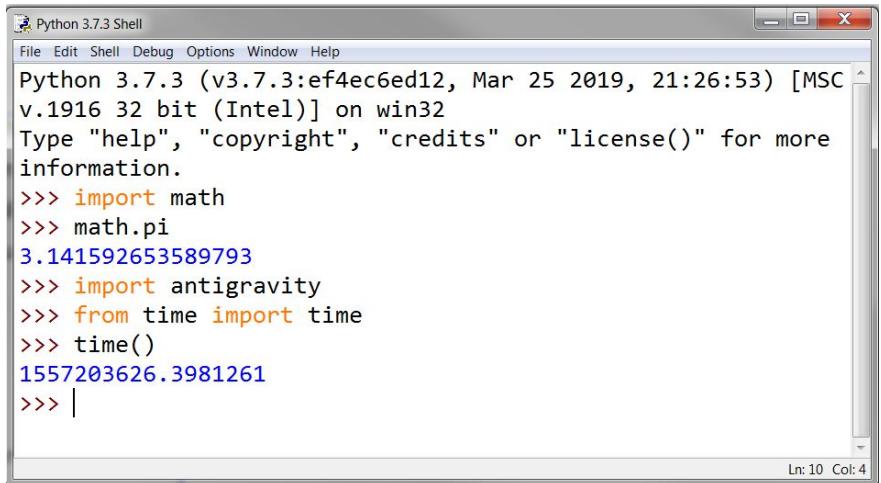

## IMPORTING

Importing is the process of loading classes from another file into your current project. There are a lot of modules (collections of classes) that come with Python, which you can import. We will also be importing Revit classes from the Revit API soon enough. The syntax is :

```
import module
```

```
from module import class
```

Start with the keyword “import” and then the module name. If you only want to insert a specific class from a module, then you can use the keyword “from” the module name, and then the keyword “import”, followed by the class name.

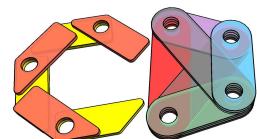

The screenshot shows the Python 3.7.3 Shell window. The title bar reads "Python 3.7.3 Shell". The menu bar includes File, Edit, Shell, Debug, Options, Window, and Help. The main area displays the following Python session:

```
Python 3.7.3 (v3.7.3:ef4ec6ed12, Mar 25 2019, 21:26:53) [MSC v.1916 32 bit (Intel)] on win32
Type "help", "copyright", "credits" or "license()" for more
information.

>>> import math
>>> math.pi
3.141592653589793
>>> import antigravity
>>> from time import time
>>> time()
1557203626.3981261
>>> |
```

In the bottom right corner of the shell window, there is a status bar with "Ln: 10 Col: 4".

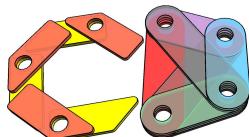

# CLASSES

## THAT'S IT!

That's all you need to know about the basic of python. You can use what you just learned to create really powerful programs, even if it doesn't seem like it as a beginner. Of course, there are a lot of extra details to learn, but this covers the majority of the language.

As you get more experience you'll learn to build bigger and bigger programs to do more complicated things with your code.

# CLASSES

## REVIT API

# WHY REVIT API?

## REVIT NODE LIBRARY

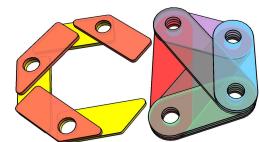

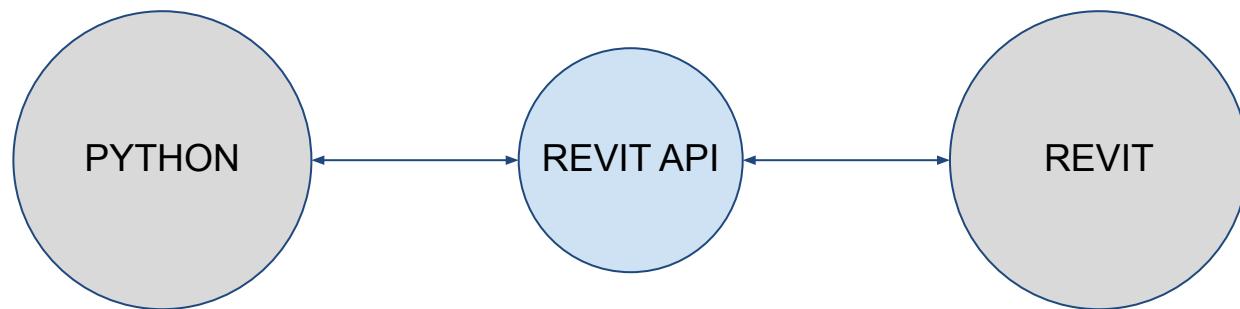

Revit Node Library provides access to many classes and methods within the revit for creating geometries and making changes to revit elements but there are still some limitations; we use Revit API to go beyond what R node and access all classes and methods within the Revit Project

```
1 # Enable Python support and load DesignScript library
2 import clr
3 clr.AddReference('ProtoGeometry')
4 from Autodesk.DesignScript.Geometry import *
5
6 clr.AddReference('RevitNodes')
7 import Revit
8
9 # The inputs to this node will be stored as a list in the IN variables.
10 dataEnteringNode = IN
11
12 # Place your code below this line
13
14 # Assign your output to the OUT variable.
15 OUT = dir(Revit.Elements)
```

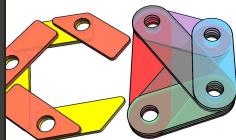

# REVIT API

## APPLICATION PROGRAMMING INTERFACE

## IMPORTING API

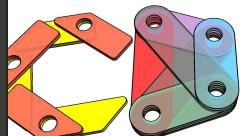

```
1 # Enable Python support and load DesignScript library
2 import clr
3 clr.AddReference('ProtoGeometry')
4 from Autodesk.DesignScript.Geometry import *
5
6 #import RevitAPI
7
8 clr.AddReference('RevitAPI')
9 from Autodesk.Revit.DB import *
10
11 clr.AddReference('RevitServices')
12 from RevitServices.Persistence import DocumentManager
13 from RevitServices.Transactions import TransactionManager
14
15 # The inputs to this node will be stored as a list in the IN variables.
16 familytype = UnwrapElement(IN[0])
17 output = []
18
19 # Place your code below this line
20 #Assign Document
21 doc = DocumentManager.Instance.CurrentDBDocument
22
23 #Start Transaction
24 TransactionManager.Instance.EnsureInTransaction(doc)
25
26
27 for x in range (0,100,10):
28     fam = doc.Create.NewFamilyInstance(XYZ(x,0,0),
29                                         familytype,Structure.StructuralType.NonStructural)
30     output.append(fam)
31
32 #End Transaction
33 TransactionManager.Instance.TransactionTaskDone()
34
35 # Assign your output to the OUT variable.
36 OUT = output
```

Document Manager Class

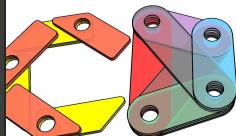

Transaction Manager Class

```
1 # Enable Python support and load DesignScript library
2 import clr

## FamilyInstanceCreationData Constructor (XYZ, FamilySymbol, StructuralType)

[FamilyInstanceCreationData Class](#) [See Also](#) [Send Feedback](#)

Initializes a new instance of the [FamilyInstanceCreationData](#) class

**Namespace:** Autodesk.Revit.Creation

**Assembly:** RevitAPI (in RevitAPI.dll) Version: 19.0.0.0 (19.2.1.1)

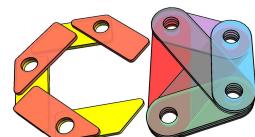

### Syntax

#### C#

```
public FamilyInstanceCreationData(  
    XYZ location,  
    FamilySymbol symbol,  
    StructuralType structuralType  
)
```

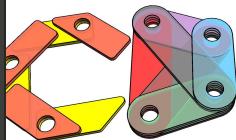

#### Visual Basic

```
Public Sub New (  
    location As XYZ, _  
    symbol As FamilySymbol, _  
    structuralType As StructuralType _  
)
```

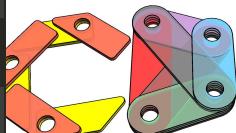

## Creating family

```
1 # Enable Python support and load DesignScript library
2 import clr
3 clr.AddReference('ProtoGeometry')
4 from Autodesk.DesignScript.Geometry import *
5
6 #import RevitAPI
7
8 clr.AddReference('RevitAPI')

```

# CLASSES

## CONTAINERS FOR FUNCTIONS AND OTHER DATA TYPES

When accessing the Revit API Python most objects are made up of classes. Classes are a collection of properties and methods.

- **Wall**

\*Properties are similar to Parameters in Revit.

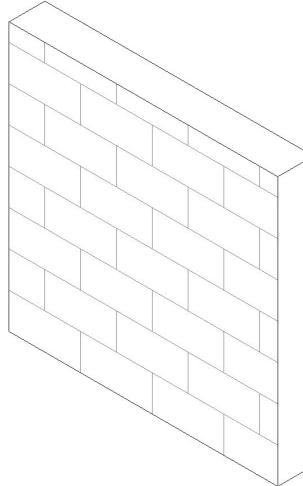

- **Wall.Name**

Methods are functions (actions) you can perform with that class. Methods are always designated with parentheses, and may require input between the parenthesis

- **Wall.Flip()**

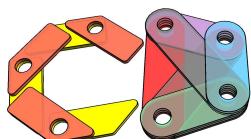

\*PROPERTY  
**Wall.Name**

CLASS  
**WALL**

METHOD  
**Wall.Flip()**

\*Technically in Python this is called an Attribute, but in .Net terminology, which the Revit API uses, it's called a Property.

# SYNTAX STRUCTURE

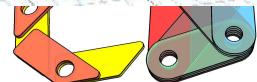

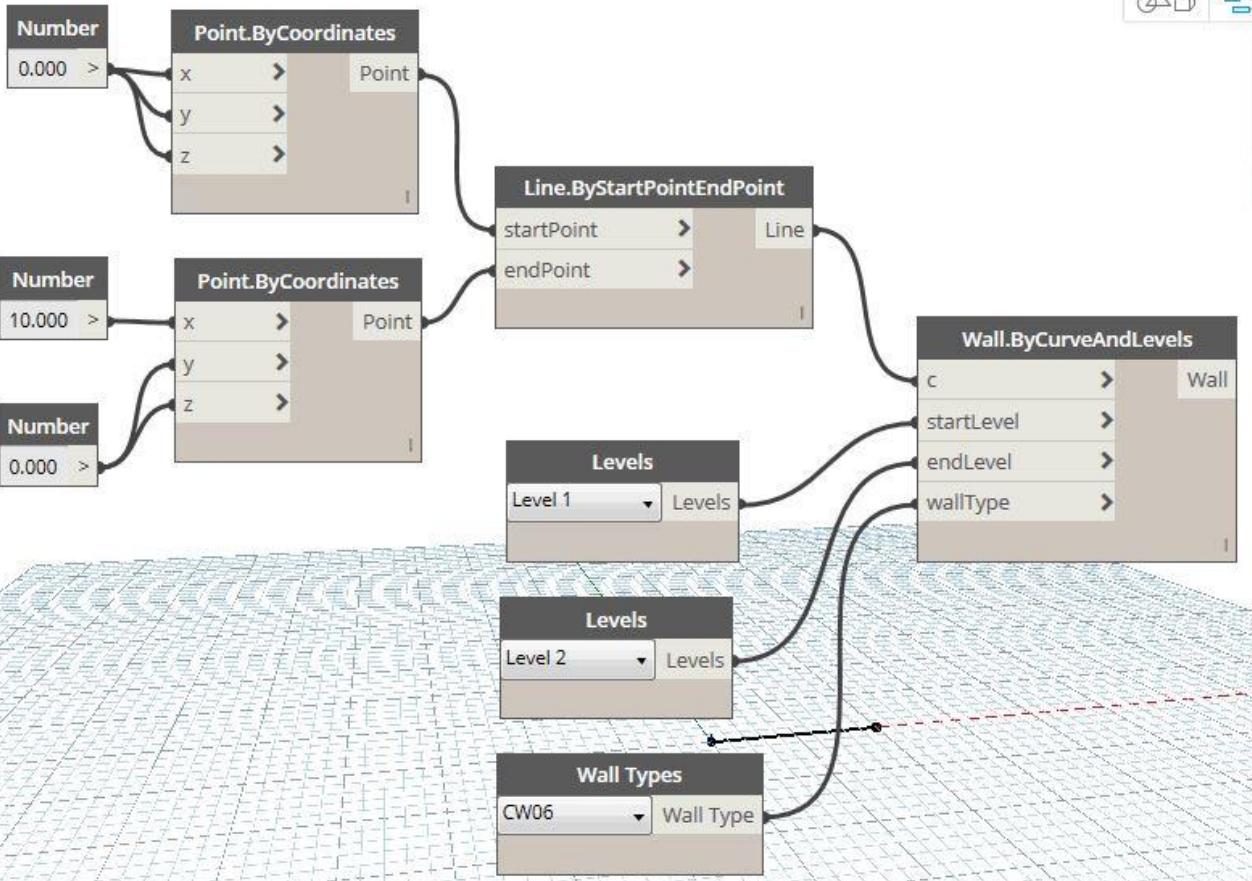

## CREATE A WALL SAMPLE

# SYNTAX

## DYNAMO NODES

Create a simple wall using Dynamo.

Recreate this in Python.

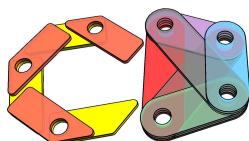

# SYNTAX

## ADD REFERENCE

Import all the modules we will need for this script.

Keep references in a .txt file and copy and past.

```
1 import clr
2 #Import module for Revit
3 clr.AddReference("RevitNodes")
4 import Revit
5 clr.ImportExtensions(Revit.Elements)
6 #import module for the Document and transactions
7 clr.AddReference("RevitServices")
8 import RevitServices
9 from RevitServices.Persistence import DocumentManager
10 from RevitServices.Transactions import TransactionManager
11 #import Revit API
12 clr.AddReference('RevitAPI')
13 from Autodesk.Revit.DB import *
14 #get the document
15 doc = DocumentManager.Instance.CurrentDBDocument
16 #Dynamo input
17 baseLevel = UnwrapElement(IN[0])
18 topLevel = UnwrapElement(IN[1])
19 wallType = UnwrapElement(IN[2])
20 #create point for line
21 pt1 = XYZ(0, 0, 0)
22 pt2 = XYZ(10, 0, 0)
23 #use safe transaction with Revit
24 TransactionManager.Instance.EnsureInTransaction(doc)
25 #create line
26 line = Line.CreateBound(pt1, pt2)
27 #create wall using Revit API
28 wall = Wall.Create(doc, line, baseLevel.Id, False)
29 #Set the wall type to Dynamo input
30 wall.WallType = wallType
31 #Get the top constraint parameter using built in parameter
32 #Revit Document shows it as WALL_HEIGHT_TYPE
33 topConstraint = wall.get_Parameter(BuiltInParameter.WALL_HEIGHT_TYPE)
34 #Set the top constraint
35 topConstraint.Set(topLevel.Id)
36 #Finish Transaction with task done
37 TransactionManager.Instance.TransactionTaskDone()
38
39 OUT = wall
```

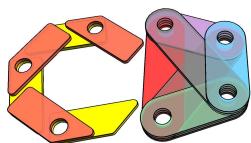

# SYNTAX

## CURRENT DOCUMENT

From the imported document manager get the instance of the current document.

```
1 import clr
2 #Import module for Revit
3 clr.AddReference("RevitNodes")
4 import Revit
5 clr.ImportExtensions(Revit.Elements)
6 #import module for the Document and transactions
7 clr.AddReference("RevitServices")
8 import RevitServices
9 from RevitServices.Persistence import DocumentManager
10 from RevitServices.Transactions import TransactionManager
11 #import Revit API
12 clr.AddReference('RevitAPI')
13 from Autodesk.Revit.DB import *
14 #get the document
15 doc = DocumentManager.Instance.CurrentDBDocument
16 #Dynamo input
17 baseLevel = UnwrapElement(IN[0])
18 topLevel = UnwrapElement(IN[1])
19 wallType = UnwrapElement(IN[2])
20 #create point for line
21 pt1 = XYZ(0, 0, 0)
22 pt2 = XYZ(10, 0, 0)
23 #use safe transaction with Revit
24 TransactionManager.Instance.EnsureInTransaction(doc)
25 #create line
26 line = Line.CreateBound(pt1, pt2)
27 #create wall using Revit API
28 wall = Wall.Create(doc, line, baseLevel.Id, False)
29 #Set the wall type to Dynamo input
30 wall.WallType = wallType
31 #Get the top constraint parameter using built in parameter
32 #Revit Document shows it as WALL_HEIGHT_TYPE
33 topConstraint = wall.get_Parameter(BuiltInParameter.WALL_HEIGHT_TYPE)
34 #Set the top constraint
35 topConstraint.Set(topLevel.Id)
36 #Finish Transaction with task done
37 TransactionManager.Instance.TransactionTaskDone()
38
39 OUT = wall
```

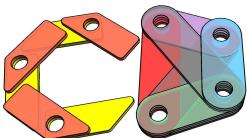

# SYNTAX

## DYNAMO INPUT

User will input base level, top level, and wall type. We've unwrapped Revit elements with RevitNodes.

```
1 import clr
2 #Import module for Revit
3 clr.AddReference("RevitNodes")
4 import Revit
5 clr.ImportExtensions(Revit.Elements)
6 #import module for the Document and transactions
7 clr.AddReference("RevitServices")
8 import RevitServices
9 from RevitServices.Persistence import DocumentManager
10 from RevitServices.Transactions import TransactionManager
11 #import Revit API
12 clr.AddReference('RevitAPI')
13 from Autodesk.Revit.DB import *
14 #get the document
15 doc = DocumentManager.Instance.CurrentDBDocument
16 #Dynamo input
17 baseLevel = UnwrapElement(IN[0])
18 topLevel = UnwrapElement(IN[1])
19 wallType = UnwrapElement(IN[2])
20 #create point for line
21 pt1 = XYZ(0, 0, 0)
22 pt2 = XYZ(10, 0, 0)
23 #use safe transaction with Revit
24 TransactionManager.Instance.EnsureInTransaction(doc)
25 #create line
26 line = Line.CreateBound(pt1, pt2)
27 #create wall using Revit API
28 wall = Wall.Create(doc, line, baseLevel.Id, False)
29 #Set the wall type to Dynamo input
30 wall.WallType = wallType
31 #Get the top constraint parameter using built in parameter
32 #Revit Document shows it as WALL_HEIGHT_TYPE
33 topConstraint = wall.get_Parameter(BuiltInParameter.WALL_HEIGHT_TYPE)
34 #Set the top constraint
35 topConstraint.Set(topLevel.Id)
36 #Finish Transaction with task done
37 TransactionManager.Instance.TransactionTaskDone()
38
39 OUT = wall
```

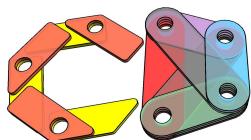

# SYNTAX

## POINTS

Create two points with arguments X Y and Z.

```
1 import clr
2 #Import module for Revit
3 clr.AddReference("RevitNodes")
4 import Revit
5 clr.ImportExtensions(Revit.Elements)
6 #import module for the Document and transactions
7 clr.AddReference("RevitServices")
8 import RevitServices
9 from RevitServices.Persistence import DocumentManager
10 from RevitServices.Transactions import TransactionManager
11 #import Revit API
12 clr.AddReference('RevitAPI')
13 from Autodesk.Revit.DB import *
14 #get the document
15 doc = DocumentManager.Instance.CurrentDBDocument
16 #Dynamo input
17 baseLevel = UnwrapElement(IN[0])
18 topLevel = UnwrapElement(IN[1])
19 wallType = UnwrapElement(IN[2])
20 #create point for line
21 pt1 = XYZ(0, 0, 0)
22 pt2 = XYZ(10, 0, 0)
23 #use safe transaction with Revit
24 TransactionManager.Instance.EnsureInTransaction(doc)
25 #create line
26 line = Line.CreateBound(pt1, pt2)
27 #create wall using Revit API
28 wall = Wall.Create(doc, line, baseLevel.Id, False)
29 #Set the wall type to Dynamo input
30 wall.WallType = wallType
31 #Get the top constraint parameter using built in parameter
32 #Revit Document shows it as WALL_HEIGHT_TYPE
33 topConstraint = wall.get_Parameter(BuiltInParameter.WALL_HEIGHT_TYPE)
34 #Set the top constraint
35 topConstraint.Set(topLevel.Id)
36 #Finish Transaction with task done
37 TransactionManager.Instance.TransactionTaskDone()
38
39 OUT = wall
```

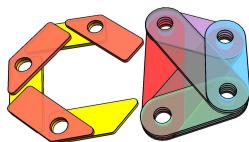

# SYNTAX

## START TRANSACTION

Using our Revit Services we use our Transaction Manager Instance to Ensure In Transaction our current document.

```
1 import clr
2 #Import module for Revit
3 clr.AddReference("RevitNodes")
4 import Revit
5 clr.ImportExtensions(Revit.Elements)
6 #import module for the Document and transactions
7 clr.AddReference("RevitServices")
8 import RevitServices
9 from RevitServices.Persistence import DocumentManager
10 from RevitServices.Transactions import TransactionManager
11 #import Revit API
12 clr.AddReference('RevitAPI')
13 from Autodesk.Revit.DB import *
14 #get the document
15 doc = DocumentManager.Instance.CurrentDBDocument
16 #Dynamo input
17 baseLevel = UnwrapElement(IN[0])
18 topLevel = UnwrapElement(IN[1])
19 wallType = UnwrapElement(IN[2])
20 #create point for line
21 pt1 = XYZ(0, 0, 0)
22 pt2 = XYZ(10, 0, 0)
23 #use safe transaction with Revit
24 TransactionManager.Instance.EnsureInTransaction(doc)
25 #create line
26 line = Line.CreateBound(pt1, pt2)
27 #create wall using Revit API
28 wall = Wall.Create(doc, line, baseLevel.Id, False)
29 #Set the wall type to Dynamo input
30 wall.WallType = wallType
31 #Get the top constraint parameter using built in parameter
32 #Revit Document shows it as WALL_HEIGHT_TYPE
33 topConstraint = wall.get_Parameter(BuiltInParameter.WALL_HEIGHT_TYPE)
34 #Set the top constraint
35 topConstraint.Set(topLevel.Id)
36 #Finish Transaction with task done
37 TransactionManager.Instance.TransactionTaskDone()
38
39 OUT = wall
```

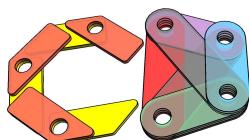

# SYNTAX

## CREATE LINE

Create a line which has two arguments. A start point and end point.

```
1 import clr
2 #Import module for Revit
3 clr.AddReference("RevitNodes")
4 import Revit
5 clr.ImportExtensions(Revit.Elements)
6 #import module for the Document and transactions
7 clr.AddReference("RevitServices")
8 import RevitServices
9 from RevitServices.Persistence import DocumentManager
10 from RevitServices.Transactions import TransactionManager
11 #import Revit API
12 clr.AddReference('RevitAPI')
13 from Autodesk.Revit.DB import *
14 #get the document
15 doc = DocumentManager.Instance.CurrentDBDocument
16 #Dynamo input
17 baseLevel = UnwrapElement(IN[0])
18 topLevel = UnwrapElement(IN[1])
19 wallType = UnwrapElement(IN[2])
20 #create point for line
21 pt1 = XYZ(0, 0, 0)
22 pt2 = XYZ(10, 0, 0)
23 #use safe transaction with Revit
24 TransactionManager.Instance.EnsureInTransaction(doc)
25 #create line
26 line = Line.CreateBound(pt1, pt2)
27 #create wall using Revit API
28 wall = Wall.Create(doc, line, baseLevel.Id, False)
29 #Set the wall type to Dynamo input
30 wall.WallType = wallType
31 #Get the top constraint parameter using built in parameter
32 #Revit Document shows it as WALL_HEIGHT_TYPE
33 topConstraint = wall.get_Parameter(BuiltInParameter.WALL_HEIGHT_TYPE)
34 #Set the top constraint
35 topConstraint.Set(topLevel.Id)
36 #Finish Transaction with task done
37 TransactionManager.Instance.TransactionTaskDone()
38
39 OUT = wall
```

# SYNTAX

## CREATE WALL

To create a wall the arguments are the current document, a curve, a level ID and structural bool.

Revit API Docs website is a great place to find the documentation on the Revit API.

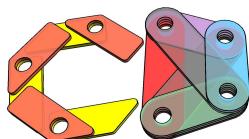

[revitapidocs.com](http://revitapidocs.com)

Revit API Docs

Online Documentation for the Revit API

```
public static Wall Create(  
    Document document,  
    Curve curve,  
    ElementId levelId,  
    bool structural  
)  
  
1 import clr  
2 #Import module for Revit  
3 clr.AddReference("RevitNodes")  
4 import Revit  
5 clr.ImportExtensions(Revit.Elements)  
6 #import module for the Document and transactions  
7 clr.AddReference("RevitServices")  
8 import RevitServices  
9 from RevitServices.Persistence import DocumentManager  
10 from RevitServices.Transactions import TransactionManager  
11 #import Revit API  
12 clr.AddReference('RevitAPI')  
13 from Autodesk.Revit.DB import *  
14 #get the document  
15 doc = DocumentManager.Instance.CurrentDBDocument  
16 #Dynamo input  
17 baseLevel = UnwrapElement(IN[0])  
18 topLevel = UnwrapElement(IN[1])  
19 wallType = UnwrapElement(IN[2])  
20 #create point for line  
21 pt1 = XYZ(0, 0, 0)  
22 pt2 = XYZ(10, 0, 0)  
23 #use safe transaction with Revit  
24 TransactionManager.Instance.EnsureInTransaction(doc)  
25 #create line  
26 line = Line.CreateBound(pt1, pt2)  
27 #create wall using Revit API  
28 wall = Wall.Create(doc, line, baseLevel.Id, False)  
29 #Set the wall type to Dynamo input  
30 wall.WallType = wallType  
31 #Get the top constraint parameter using built in parameter  
32 #Revit Document shows it as WALL_HEIGHT_TYPE  
33 topConstraint = wall.get_Parameter(BuiltInParameter.WALL_HEIGHT_TYPE)  
34 #Set the top constraint  
35 topConstraint.Set(topLevel.Id)  
36 #Finish Transaction with task done  
37 TransactionManager.Instance.TransactionTaskDone()  
38  
39 OUT = wall
```

# SYNTAX

## SET PARAMETER

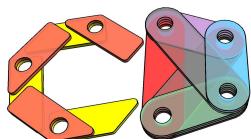

The `get_Parameter` method which needs the built in parameter name. We can find the name in the Revit API Doc website.

"Top Constraint"

WALL\_HEIGHT\_TYPE

```
1 import clr
2 #Import module for Revit
3 clr.AddReference("RevitNodes")
4 import Revit
5 clr.ImportExtensions(Revit.Elements)
6 #import module for the Document and transactions
7 clr.AddReference("RevitServices")
8 import RevitServices
9 from RevitServices.Persistence import DocumentManager
10 from RevitServices.Transactions import TransactionManager
11 #import Revit API
12 clr.AddReference('RevitAPI')
13 from Autodesk.Revit.DB import *
14 #get the document
15 doc = DocumentManager.Instance.CurrentDBDocument
16 #Dynamo input
17 baseLevel = UnwrapElement(IN[0])
18 topLevel = UnwrapElement(IN[1])
19 wallType = UnwrapElement(IN[2])
20 #create point for line
21 pt1 = XYZ(0, 0, 0)
22 pt2 = XYZ(10, 0, 0)
23 #use safe transaction with Revit
24 TransactionManager.Instance.EnsureInTransaction(doc)
25 #create line
26 line = Line.CreateBound(pt1, pt2)
27 #create wall using Revit API
28 wall = Wall.Create(doc, line, baseLevel.Id, False)
29 #Set the wall type to Dynamo input
30 wall.WallType = wallType
31 #Get the top constraint parameter using built in parameter
32 #Revit Document shows it as WALL_HEIGHT_TYPE
33 topConstraint = wall.get_Parameter(BuiltInParameter.WALL_HEIGHT_TYPE)
34 #Set the top constraint
35 topConstraint.Set(topLevel.Id)
36 #Finish Transaction with task done
37 TransactionManager.Instance.TransactionTaskDone()
38
39 OUT = wall
```

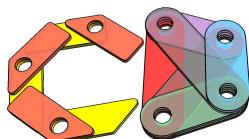

# SYNTAX

## TRANSACTION DONE

Complete our transaction using  
Transaction Manager Instance  
Transaction Task Done.  
Then we send out our new wall.

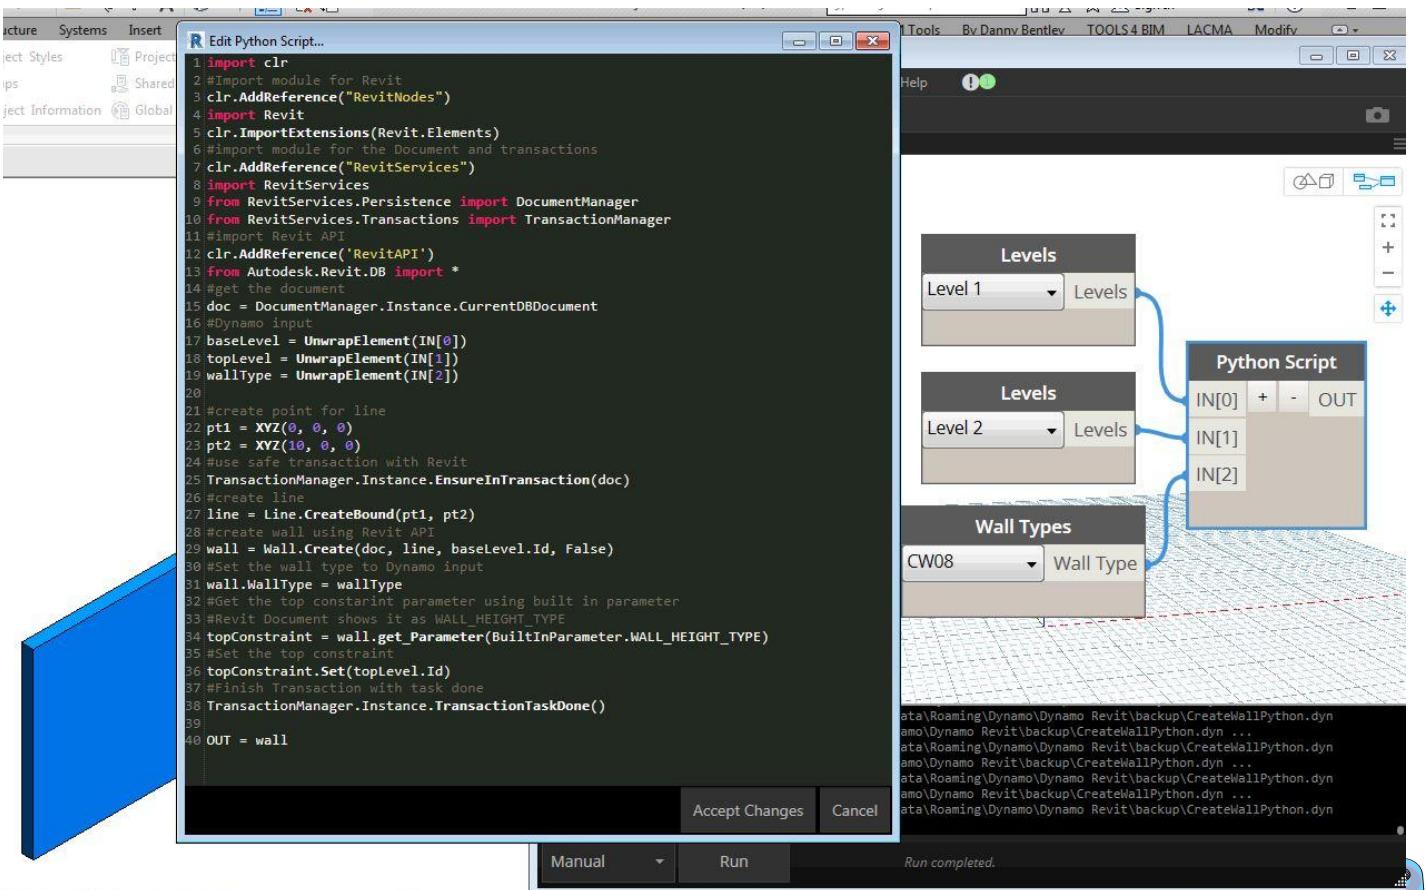

```
1 import clr
2 #Import module for Revit
3 clr.AddReference("RevitNodes")
4 import Revit
5 clr.ImportExtensions(Revit.Elements)
6 #import module for the Document and transactions
7 clr.AddReference("RevitServices")
8 import RevitServices
9 from RevitServices.Persistence import DocumentManager
10 from RevitServices.Transactions import TransactionManager
11 #import Revit API
12 clr.AddReference('RevitAPI')
13 from Autodesk.Revit.DB import *
14 #get the document
15 doc = DocumentManager.Instance.CurrentDBDocument
16 #Dynamo input
17 baseLevel = UnwrapElement(IN[0])
18 topLevel = UnwrapElement(IN[1])
19 wallType = UnwrapElement(IN[2])
20 #create point for line
21 pt1 = XYZ(0, 0, 0)
22 pt2 = XYZ(10, 0, 0)
23 #use safe transaction with Revit
24 TransactionManager.Instance.EnsureInTransaction(doc)
25 #create line
26 line = Line.CreateBound(pt1, pt2)
27 #create wall using Revit API
28 wall = Wall.Create(doc, line, baseLevel.Id, False)
29 #Set the wall type to Dynamo input
30 wall.WallType = wallType
31 #Get the top constraint parameter using built in parameter
32 #Revit Document shows it as WALL_HEIGHT_TYPE
33 topConstraint = wall.get_Parameter(BuiltInParameter.WALL_HEIGHT_TYPE)
34 #Set the top constraint
35 topConstraint.Set(topLevel.Id)
36 #Finish Transaction with task done
37 TransactionManager.Instance.TransactionTaskDone()
38
39 OUT = wall
```

# SYNTAX

## COMPLETE CODE

It's not so intimidating.

# PROJECT WORKFLOW WITH PYTHON & DYNAMO

BY DANNY BENTLEY

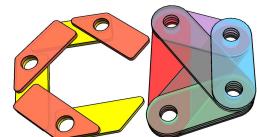

## READ CSV FILE

USING CSV FILE TO  
CREATE AN OBJECT CLASS.

Read file using the system, input/output, stream reader  
**System.IO.StreamReader(filePath)**

return byte from the stream. If -1 nothing left to read  
**Peek()**

Close file  
**Close()**

# CREATE STRUCTURAL FRAMING

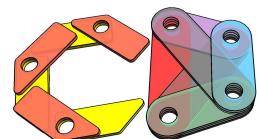

USING OBJECT DATA TO  
CREATE REVIT  
STRUCTURAL FRAMING  
ELEMENTS.

Collect all levels in project to host new framing  
**FilteredElementCollector(doc)**  
**.OfCategory(BuiltInCategory.OST\_Levels)**  
**.WhereElementIsNotElementType().ToElements()**

Collect structural framing types to set new framing type  
**FilteredElementCollector(doc)**  
**.OfCategory(BuiltInCategory.OST\_StructuralFraming)**  
**.OfClass(FamilySymbol).ToElements()**

Create a new family instance in Revit.

**NewFamilyInstance(XYZ, FamilySymbol, Level, StructuralType)**

## UPDATE STRUCTURAL FRAMING

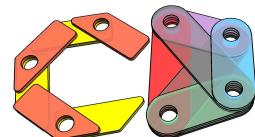

USING OBJECT DATA TO  
UPDATE REVIT  
STRUCTURAL FRAMING  
ELEMENTS.

Dictionary of key CSV Id and value Revit Element

```
dict = {}  
dict.Add(key, value)
```

Set new type to element

```
Element.Symbol = type
```

## GRAPHIC OVERRIDE

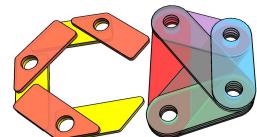

SET GRAPHIC OVERRIDE IN  
A VIEW.

Setting to override display of elements in a view  
**OverrideGraphicSettings()**

Set the color of the surface foreground pattern  
**SetProjectionFillColor(Color)**

Sets the ElementId of the surface foreground pattern  
**SetProjectionFillPatternId(ElementId)**

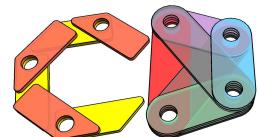

Set new type to element  
**Element.Symbol = type**

## ROTATE ELEMENTS

ROTATE A GROUP OF  
ELEMENTS IN A PROJECT

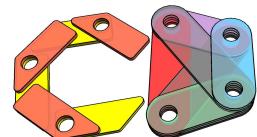

Rotates a set of elements about a given axis and angle  
**ElementTransformUtils**  
**.RotateElements(Document, ICollection<ElementId>,  
Line axis, double angle)**

## MOVE ELEMENTS

MOVE A GROUP OF  
ELEMENTS IN A PROJECT

Rotates a set of elements about a given axis and angle  
**ElementTransformUtils**  
**.MoveElements(Document, ICollection<ElementId>, XYZ)**

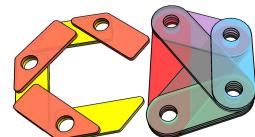

## CREATE SHEETS

CREATE NEW SHEETS AND  
SET THE NAME AND  
NUMBER PARAMETERS

ViewSheet class and Create method  
**ViewSheet**  
**.Create(Document, ElementId titleblock)**

Set sheet number  
**newSheet.SheetNumber = sheetNumber**

Set sheet name  
**newSheet.Name = sheetName**

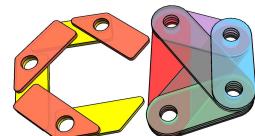

## APPLY VIEW TEMPLATE

APPLYING VIEW  
TEMPLATES TO MULTIPLE  
VIEWS.

Collect all the views from project  
**FilteredElementCollector(Document).OfClass(View)**

Test view to ensure it's a view template  
**view.IsTemplate**

Set view template onto a view  
**view.ViewTemplateId = viewTemp.Id**

## COPY LINKED MODEL ELEMENTS

COPY ELEMENTS FROM A  
LINKED MODEL TO THE  
CURRENT MODEL

Collect all linked models in project  
**FilteredElementCollector(Document)  
.OfClass(RevitLinkInstance)**

Return the linked model document  
**linkDoc.GetLinkedDocument**

Get's the total transform, which includes the true north  
transform for instances like import instances  
**linkDoc.GetTotalTransform()**

A collection of utilities allowing transformation of  
elements. Copies a set of elements from source document  
to destination document

**ElementTransformUtils**  
**.CopyElements(Document linkedDoc, ICollection<ElementId>,  
Document currentDoc, Transform,  
CopyPasteOptions)**
